PREFACE.

Soon after my appointment to the Chair of Chemistry at St. Mary's Hospital in 1854, I noticed that the chief part of the lecture-time was occupied by the most diligent students in taking notes of the various formulæ and reactions which were from time to time stated; and that they were thereby prevented from paying continuous attention to the course of the Lecture, and its illustrative experiments.

To remedy this evil, I published in 1855 the first edition of my "Notes for Students," in which I endeavoured to supply all the information necessary to form a connecting basis for the teaching in the lectures.

In the present edition, the "Analytical Notes for Students" have been omitted, in order to allow of increased space: these Analytical Notes will be published separately.

ALBERT J. BERNAYS.

Chemical Laboratory, St. Thomas's Hospital Medical College.

BERNAYS'S NOTES

FOR

STUDENTS IN CHEMISTRY.

Manifold as are the substances which we meet with on every hand, there are but few bodies which cannot be resolved by heat or otherwise into simpler forms. Such as resist all attempts at decomposition are called Elements or simple bodies.

The quantities of one element which can unite with a constant quantity of another, increase by successive steps, according to simple numerical ratios. Thus, two parts by weight of Hydrogen can unite with sixteen parts by weight of oxygen, and further with thirty-two parts by weight of the same element Oxygen. This fact has led to the idea that the elementary bodies are made up of indivisible particles called Atoms, each having a constant weight peculiar to itself. A collection of elementary atoms united together to form a compound, constitutes a Molecule, the weight of which is equal to the weight of the sum of its component atoms. Thus an atom of Oxygen weighing 16 unites with 2 atoms of Hydrogen, each atom weighing 1, to form a molecule of hydrogen oxide or Water, weighing 16 + 2 = 18.

These combinations are represented by symbols, the initial letter of the element denoting the atom. Thus Iodine is represented by I; it unites with Hydrogen H, to form a compound, the molecule of which is expressed by the letters HI. A group of two or more atoms is expressed by a numeral either before the symbol, or by a small numeral to the right of the symbol. Thus 2I or I₂ denote 2 atoms of Iodine; but I₂O₃ indicates a com-

pound of 2 atoms of iodine with 5 atoms of oxygen.

When one element takes the place of another in combination, the substitution always occurs in proportions which are fixed, definite and invariable. The relative quantities of different elements which thus replace one another, are called Equivalents or Chemical Equivalents: they are either identical with the atomic weights, or simple multiples or submultiples of them. When Zine takes the place of Hydrogen, the quantity of Zine is

only one-half its atomic weight; but, when potassium does so the equivalents are in the same proportion as their atomic weights.

Chemical reactions may be represented symbolically in the form of equations, the symbols of the reagents being placed to the left, and those of the results on the same line to the right. only separated by \doteq . Thus: $K_2 + OH_2 = OK_2 + H_2$. this ease, the molecule of KALIUM (potassium) decomposes the molecule of WATER, into the molecule of POTASSOXIDE, and the molecule of hydrogen. Multivalent elements often exhibit varying degrees of equivalency. Thus Carbon is quadrivalent in CII, and bivalent in CO. Nitregen is univalent in NoO, trivelent in N2O2 and quinquivalent in N2O5. The variation

mostly takes place by two units of equivalency.

The atomic weights of those elements which are known to exist as gas or vapor, are, as a rule proportional to their specific gravities. Taking the specific gravity of hydrogen as I, then are the sp. grs. of Oxygen, Nitrogen, Chlorine and Fluorine, and of the vapors of Bromine, Iodine, Sulphur, Selenium and Tellurium (compared under the same conditions of temperature and pressure), identical with their atomic weights. Exceptions to this rule are exhibited by arsenicum and phosphorus, whose vapor-densities are twice their atomic weights, and by Cadmium and Mercury, whose vapor-densities equal only half their respective atomic weights. With these exceptions, the combining volumes of all elementary gases are equal. The molecules of compound bodies in the gascous state occupy the space of two volumes of hydrogen. As the molecule of an elementary gas is made up of two atoms, it may be said that equal volumes of all gases contain equal numbers of molecules, or, that the molecules of all gases occupy equal volumes (Law of Avogadro). Thus is afforded a sure mode of fixing the molecular constitution of all compounds obtainable as gases, and of ascertaining the atomic weights of the elements.

When it is said that the sp. gr. of any compound gas or vapor, referred to hydrogen as unity, is equal to half its atomic or molecular weight, it must be remembered flut a few exceptions are known. Thus ammonium chloride ClH4N, occupies, as vapor, four fimes the space of an atom of hydrogen. The same exceptions we have in the eases of Phosphoric Chloride Cl₅P; OIL OF VITRIOL SO₂(OH)₂; MERCURGUS CHLORIDE Hg₂Cl₂; AMMO-NIUM HYDROGEN SULPHIDE SH(H,N), &c. &c. And, to a certain extent, the explanation may lie in the supposition, that the high temperature to which they are subjected brings about a partial

decomposition or "dissociation."

If one or more of the atoms of a fully saturated molecule be removed, it is obvious that the residue will be no longer saturated: such residues are called Radicles. In the ease of the tetrad Carbon, the saturated hydrogen compound is known as METHANE CH₄; the removal of one atom of hydrogen, leaves a residue known as METHYL CH₃. A further removal of an atom of hydrogen, leaves a bivalent radicle METHENE CH₂. If we take away three atoms of hydrogen from METHANE CH₄, we obtain the trivalent radicle METHENYL CH. Lastly, when all the hydrogen is removed, we have the tetrad Carbou remaining. So likewise with the saturated molecule hydrogen oxide or water OH₂; take away an atom of hydrogen, and we have a monad radicle hydroxyl OH, analogous to chlorine, &c.

The atomic weight of an element is, then, in some cases identical with its equivalent; in other eases equal to two, three, four, five times, &e., its equivalent weight. In other words, one atom of an element may displace or be substituted for 1, 2, 3, 4, 5, 6 atoms of hydrogen. This difference in combining or saturating power is called Atomicity or Quanti-

valence.

The elements are 64 in number, and may be arranged according to their quantivalence. They are either monads, dyads, triads, tetrads, pentads, or hexads; either univalent, bivalent, trivalent, quadrivalent, quinquivalent or sexvalent. Elements of even equivalency are ealled artiads; of uneven, perissads.

ALPHABETICAL TABLE OF THE ELEMENTS, SYMBOLS, and ATOMIC WEIGHTS.

Selenium and Tellurium, which are bracketed, are of no importance except to students of Chemistry. Hydrogen is, properly speaking, a metal; but this division of the elements is only retained because of the requirements of certain Universities.

I. Oxygen 0 = 16. $0_2 = 32$.

A dyad element. Colorless, tasteless and inodorous gas; uninflammable. A great supporter of combustion. Necessary to respiration, decay, germination, and the commencement of putrefaction. The most magnetic of gases: the diarnal variations of the needle referable to the effects of heat upon it. Oxygen is 16× heavier than its own volume of hydrogen. One litre weighs 1.437 grammes; 11.19 litres weigh 16 grammes (one gramme is equal to 15.432 grains, and one litre to 1.76 pints). Compared with dry air it has a relative weight or specific gravity of 1.1056: one hundred cubic inches weigh 34.29 grains at 15°.5 C. and 30" bar. In water it is very little soluble; 100 vols. dissolve 2.99 vols. at 15° C., and 4.11 vols. at 0° C. In the free state, or native, oxygen constitutes 21 per cent. by measure, and 23 per cent. by weight of dry air. Combined with Hydrogen, in the form of Water OII₂, it forms § of the weight of the latter.

It is a constituent of most minerals, and of a great number of

organie compounds.

When bodies are burnt in oxygen, they oxydize, and increase in weight. Thus at a temperature of 315°, Mcrcury (Hydrargyrum Hg) slowly oxydizes and becomes red in colour, and when further heated gives off oxygen again. Priestley in 1774 first prepared oxygen from MERCURIC OXIDE. Prep. 1. From mercuric oxide HgO, by heat: 2HgO = 2Hg + 0₂. 2. From manganese dioxide MnO2, by heat: MANGANOUS-MANGANIC OXIDE Mn_3O_4 remains. $3MnO_2 = Mn_3O_4 + O_6$. One kilogramme (2.2 lbs., each pound of 7000 grains) of the ore will yield about 50 litres of oxygen. 3. From barium dioxide BaO2, by heat; BARIUM ONIDE BaO remains. $2BaO_2 = 2BaO + \mathbf{0}_2$. 4. From hydrogen oxide OH2 by electrolysis; oxygeu separates, because the electro-negative element, at the positive pole or platinode. 4. From potassium (kalium) chlorate KClO3 by heat: POTAS-SIUM CHLORIDE KCl remains. 2KClO₃ = 2KCl + 30₂ (the chemical action is more correctly: 1. 2ClO₂OK = ClK + ClO₃OK + $\mathbf{0}_2$. 2. $\text{ClO}_3\text{OK} = \text{ClK} + 2\text{O}_2$). [122.6 parts by weight of potassium chlorate will yield 48 parts by weight of oxygen. One hundred parts therefore: 122.6:100::48:x=39.15.] For other methods, see also hydrogen sulphate SO₀(OH), manganese DIOXIDE MnO,; POTASSIUM DICHROMATE Cr.O.K.; and POTASSIUM CHLORATE ClO₂(OK), p. 20.

Ozone $O_2O=2$ vols. An allotropic modification of oxygen, or oxygen under different physical and chemical aspects. By Schönbein. Best prepared by Siemens' induction coil, iu action, upon oxygen. Also by moist phosphorus upon air or oxygen. Gas of peculiar metallic odor, insoluble in water, in alkaline and acid solutions. Absorbed by solution of potassium iodide KI. Irritates respiratory organs. Instantly decomposed at 290° into oxygen gas; two volumes into three. Is contained in minute quantities in pure air, but is instantly removed by putresceut matter. A grand oxydizing agent: bleaches also and disinfects. Iron, mercury, copper and iodine are oxydized by it, and so is also silver leaf if ozone moist. Best test for ozone is a paper soaked in solution of potassium iodide and starch: the liberated iodine blues the paper. Thus: $O_2O + 2KI + OH_2 = 2HOK$

 $+ O_2 + I_2$.

II. Hydrogen H=1. $H_2=2$.

A monad element: the standard of atomic weights. Colorless, tasteless and inodorous gas, at least when pure. Inflammable when heated in air or in oxygen, burning into Hydrogen oxide or water OH₂. The lightest of all gases. Its density as compared with air 0.0691. One litro weighs only 0.0896 of a

gramme; 11.19 litres weigh one gramme at o°C., and 760 millimetres bar. 100 c. ii. weigh 2.14 grains. [The weight of one Litre 0.0896, or say 9 Centigrammes, is called a Crith by Hoffmann. In these "Notes," preference is given to Dr. Williamson's standard, the weight of one Gramme of Hydrogen = 11.19 litres.] Hydrogen, like oxygen, has never been liquefied. Water dissolves only 1.93 per cent at 15° C.

Meteoric iron generally contains Hydrogen, and indeed the latter constitutes the chief element in the atmosphere of a numerous class of stars. H penetrates iron and platinum tubes at a red-heat. Palladium foil condenses 643 times its volume of hydrogen below 100° C., and Palladium-sponge 90 vols. This

absorption called Occlusion.

The diffusive power of Hydrogen is very high. The diffusive power varies inversely as the square root of the density of the gas. Thus the respective densities of hydrogen and oxygen are as 1 to 16; their relative rates of diffusion are as the square roots of these numbers. The rates of Effusion of gases, or the rate of passage through a minute aperture in a thin plate of metal or other substance into vacuum, follow the same law as their rates of diffusion.

Hydrogen is found chiefly in combination with oxygen in water and in nearly all organic compounds. It is separated from HYDROGEN OXIDE OH2, either by clectrolysis, or by the action of certain other metals possessed of a stronger affinity. Prep. of hydrogen. 1. From OH, by electrolysis: as a metal or the electro-positive element, H, separates at the zincode or negative pole. 2. From WATER in the form of steam, when passed over red-hot iron; ferrous-ferric oxide Fe3O4 remains. Fe3+ $4OH_2 = O_4Fe_3 + 4H_2$. 3. From water by the action of Natrium (sodium) Na. SODIUM HYDROXIDE NaOH is found in solution. $Na_2 + 2OH_2 = 2NaOH + H_2$. 4. By action of zinc upon HYDROGEN CHLORIDE CIH; ZINC CHLORIDE ZuCl2 is found in solution. $Zn + 2ClH = ZnCl_2 + H_2$. 5. Also by the action of ZING UPON HYDROGEN SULPHATE SO, H2 diluted with water: ZING SULPHATE SO_4Zn remains. $Zn + SO_4H_2 + water = SO_4Zn +$ water $+ \mathbf{H}_{a}$.

Compounds of H with 0.—1. Hydrogen oxide $0H_2 = 18$. Water is a clear transparent fluid, colorless, but of a blue tint in mass. Below o° C. it freezes and crystallizes in rhombohedra and in six-sided prisms. At 100° C., and Bar. 30" it boils, having a vapor possessed of the same elasticity as the air. Vapordensity compared with air 0.625, compared with H = 9. Increased pressure raises the boiling-point, and so does also the presence of a solid, &c. Maximum density at 4° C. Sp. gr. of icc 0.94. One litre of water at 4° C., weighs 1000 grammes. [One c.i. of water at 16°.6 C., weighs 252.456 grs., and a cubic foot 997

oz. avoirdupois. N.B. 437.5 grs. to one oz. and 7000 grs. to one lb. avoirdupois.] One imperial Gallon weighs 70,000 grs. or 10 lbs. avoirdupois. Water is 825 times heavier than air. Latent heat of water 79° C.; latent heat of steam at 100° C., 537° C. In the state of vapor, water consists of two vols. of H and one vol. of O condensed into two vols. Water is a great solvent of solids, liquids and gases, especially of the latter. As the air is a mixture, and the oxygen is more soluble than nitrogen, at 10° C, the ratio of admixture is 35 vols. of 0 to 69 of N. Many oxides unite with water to Hydroxides with great heat: thus, POTASSIUM HYDROXIDE OF HYDRATE KOH. Many salts (anhydrous) unite with water without alteration of atomic arrangement: Water of Crystallization which is easily removed by heat. Cryohydrates exist only below oo C.; e.g. NH4Cl, 12OH2. Loss of water by a salt, Efflorescence; attraction of water, Deliquescence. Substances of great diffusibility called by Graham Crystalloids; of low, Colloids. Separation, by Dialysis. 2. HY-DROGEN PEROXIDE 02H2 or DI-HYDROXYL. A liquid of sp. gr. 1.453 discovered by Thénard in 1818. Resembles chlorine feebly. Begins to give off 0 at 20° C., and the whole at 100° C., being reduced to water. Bleaches litmus. Oxydizes black SPb to white SO, Pb. Oxides of silver, gold and platinum, reduced to metals. Silver oxide AgoO + Hydrogen Peroxide OoH = $Ag_2 + OH_2 + 0_2$. One molecule of each is separated. Peroxides similarly evolve 0 and are reduced to lower oxides. This is well seen in the ease of ozone and hydrogen peroxide: O2O + O2H2 = OH₂ + 2O₂. Prep. From Barium Peroxide BaO₂ in presence of water and hydrogen chloride. BaO2 + OH2 + 2ClH = BARIUM CHLORIDE Cl., Ba $+ OH_1 + O_2H_2$.

III. Nitrogen N = 14. $N_2 = 28$.

Also called Azote. Triad element in ammonia H_3N : pentad in N_2O_5 : monad in N_2O . Colorless, tasteless, inodorous gas: uninflammable; incombustible in air, and not a supporter of combustion. Discovered by Rutherford in 1772. [Lighter than air: 0.972. One hundred c.ii. at 0° C., weigh 30.935 grs.] 11.19 litres weigh 14 grammes. 100 vols. of water dissolve 2.03 vols. at 0° C., and 1.48 vols. at 15° C. Practically, N is one-half as soluble as 0.

Atmospheric air is a MIXTURE of nitrogen with oxygen, in the ratio, when dry, of 79 vols. of N with 21 vols. of 0. Prep. Dependent upon the easy removal of oxygen from air by combnstion of phosphorus; or by passing air over red-hot copper, when copper oxide CuO remains. 2. By heating Ammonium NITRITE $NO(ONH_4)$, when water and nitrogen alone result: $NO(ONH_4) = 2OH_2 + N_2$. 3. Also by passing Chlorine gas through solution

of Ammonia H_3N . Thus: $3Cl_2 + 2NH_3 = 6ClH + N_2$. 4. An alkaline solution of Pyrogallic Acid $C_6H_6O_3$, may also be employed for removing oxygen from the air; see 'Organic Chemistry.' 5. By mixing air with hydrogen, and detonating with electric

spark: EUDIOMETER.

Compounds. Nitrogen with hydrogen. Ammonia Han or NHa = 17. Colorless, irrespirable gas, of pungent odor, exciting to tears. Feebly combustible owing to the hydrogen with pale greenish flame. Alkaline reaction. Sp. gr. of gas compared with air 0.589. 11.19 litres weigh 8.5 grammes. Under pressure of 6.5 atmospheres at 15° C., into a colorless liquid. Very soluble in water and in aleohol. Water dissolves 1180 times its vol. at o° C.: 898 times at 10° C., and 727 vols. at 15° C. Its solution in water is a valuable re-agent; the strongest has sp. gr. 0.88, contains 36 per cent. by weight, and boils at 54° C. Such solution, colorless, completely volatile, does not precipitate calcium hydroxide, nor argentum nitrate when super-saturated with hydrogen nitrate (absence of chloride), nor barium chloride (absence of sulphate). H₃N is produced in respiration, as well as in the decay and combustion of all nitrogenized bodies. Prep. From equal weights of AMMONIUM CHLORIDE CIH, N, and CALCIUM OXIDE OCa: CALCIUM CHLORIDE Cl₂Ca, WATER OH₂ and Ammonia H₃N result. 2H₄NCl + OCa = Cl₂Ca + OH₂ + 2H₃N. Slaked lime or ealeium hydroxide CaO,OH, or CaH,O, may also be used. [Students should accustom themselves to various modes of writing symbols.]

Annonia may unite directly with certain salts of hydrogen, as with hydrogen chloride HCl, to ammonium chloride NH₄Cl, or to ammonia hydrochloride NH₃HCl (4 vols.). In water it behaves like a hydroxide NH₄0H, in which hypothetical ammonium NH₄ is united with hydroxyl 0H. [Hydroxylamine NH₂0H or NH₃O is intermediate. It may be formed by the direct union of nitrogen oxide NO with H, and also by the action of H upon nitric acid NO₂OH. Thus: NO₂OH + $_3$ H₂ = $_2$ OH₂ + NH₂0H. Very volatile, decomposable base. Gives grassgreen precipitate with cupric sulphate, and decolorizes animon-

iacal euprie sulphate.]

Nitrogen with oxygen. 5 compounds: N₂O₃, N₂O₄, N₂O₃, N₂O₄, N₂O₅. [Nitric Anhydride N₂O₅. Right rhombic prisms, brilliant, colorless. Fuse at 85° C., boil at 113° C., and decompose. With OH₂ into hydrogen nitrate or nitric acid: N₂O₅ + OH₂ = 2NO₂OH. Prep. by Chlorine upon Argentum nitrate NO₂OAg. Thus: 2Cl₂ + 4NO₂OAg = 4ClAg + O₂, + 2N₂O₅.] Nitric acid or hydrogen nitrate NO₂OH or HNO₃ = 63. The aqua fortis of the alchemists. Fuming, corrosive liquid of sp. gr. 1.52 at 15° C., boils at 85° C. By Cavendish in 1785. May be called a salt of hydrogen or of the radicle hydroxyl, as is the ease with all acids. Freezes at -40° C.

Stains the skin yellow. An escharotie. Cannot be distilled without partial decomposition. Yellow color due to NoO3 in solution. Monobasic Acid, as it contains only one atom of displaceable Hydrogen H, or Hydroxyl OH. All its salts soluble in water, except trisnitrato of bismuth. When the acid of 1.52 is boiled, oxygen and nitrous anhydride are evolved, the boiling-point rises to 121° C, and an acid distils of composition approaching to 2NO2OH, 3OH2: not a true hydrate, but stable under ordinary pressures. Silver, eopper, mereury, are changed into nitrates, with evolution of orange fumes, when heated with nitrie acid. It bleaches solution of indigo in hydrogen sulphate, and in a free state browns solution of ferrous sulphate. Prep. from sodium nitrate NO2ONa by distillation with SULPHURIO ACID SO2(OH)2. Thus: NO2ONa + SO₂(0H)₂ = SO₂OHONa + NO₂0H. Better from sodinm than potassium nitrate, because at. weight of sodium is 23, and that of potassinm is 39.1. Potassium nitrate NO20K is saltpetre. SODIUM NITRATE NO. ONa is cubic nitre. AMMONIUM NITRATE, NOOONH4 is used in making nitrous oxide ON2. 2. NITROUS OXIDE, $0N_2$ or $N_20 = 44$. Also Monoxide or laughing gas. Colorless inodorous gas, of sp. gr. 1.527. Sweetish smell and taste. 100 vols. of water at oo C. dissolve 130 vols. of the gas. Under pressure of 50 atmospheres at 7° C., reducible to a colorless liquid, which freezes at -99° C., and boils at -92° C. The gas supports combustion. Much used as anæsthetie in dentistry. By repeated heating into 2 vols. of N, and I vol. of O. When potassium heated in it, Potassoxide OK_2 and N_2 result. Prep. of the gas: I. By heating AMMONIUM NITRATE NOONH, above 230° C., it breaks up into water and nitrous oxide: $NO_{2}ONH_{1} = 2OH_{2} + 0N_{2}$. 2. By dilute nitric acid upon zine; zinc nitrate, water, and nitrous oxide result. $10NO_2OH + 4Zn + nOH_2 = 4[(NO_2)_2O_2Zn]$ + $0N_2 + nOH_2 + 5OH_2$. 3. NITRIC OXIDE OF NITROSYL N0 = 30. A colorless gas of sp. gr. 1.039. Irrespirable, suffocating. Very stable. Supports burning of lighted phosphorus. Absorbed by Ferrous sulphate SO2O2Fe to olivebrown compound 2[SO₂(O₂Fe)],NO. Neither acid nor alkaline. A test for free oxygen, with which it unites to NITROGEN TRIOXIDE NoO2, OF NITROGEN PEROXIDE NO2, according to the amount of oxygen employed, with production of orange-eolored gas. Prep. of No. By the action of Cu upon hydrogen nitrate: copper nitrate, water, and nitrosyl result. 3Cu + $8 \text{ NO}_2 \text{OH} = 3 \left[(\text{NO}_2)_2 \text{O}_2 \text{Cu} \right] + 4 \text{OH}_2 + 2 \text{NO}.$ 4. NITROGEN TRIONIDE, OF NITROUS ANHYDRIDE N203. At - 18°, a thin, mobile blue liquid, which gives off orange vapors. At ordinary temperatures a vapor, prepared by mixing four volumes of Nitrosyl NO with one volume of oxygen $2NO + O = N_2O_3$. Mixed with little water, into NITROUS ACID NO(OH). Thus: $N_2O_3 + OH_2 = 2NO(OH)$. But, with more water, into nitrie oxide or nitrosyl and nitric acid. $3N_2O_3 + OH_2 = 4NO +$ 2NO₂OH. Prep. as above. [Also by nitric acid upon arsenious anhydride As_2O_3 . Thus: $As_2O_3 + 2NO_2OH + 2OH_2$ = $2[AsO(OH)_3] + N_2O_3$. Ammonia becomes nitrous aeid in contact with heated platinum or platinum black. Copper also effects the change in presence of air. Acidulated solutions of nitrites bleach permanganates. Nitrites detected by added hydrogen chloride with starch and potassium iodide. Dilute hydrogen sulphate, together with ferrous sulphate may be employed: immediate browning. 5. NITROGEN PEROXIDE NO. = 46. In prismatic crystals, which melt at - 9° C. to a mobile liquid of greenish-yellow tint; boils at 22° C. Vapor red-brown, deepening with risc of temperature. Indeed, at low temporatures it is a TETROXIDE N.O.; at higher, above 154° C., a DIOXIDE or PEROXIDE NO.. Largely contained in the nitrous acid of commerce. Decomposed by little water, so as to yield nitric and nitrous acids, $2NO_2 + OH_2 = NO_2OH$ + NOOH. By excess of water, into hydrogen nitrate and nitrosyl: $3 \text{ NO}_2 + \text{OH}_2 = 2 \text{NO}_2 \text{OH} + \text{NO}_2$ Prep. 7. By mixing 2 vols. nitric oxide with 1 vol. of oxygen NO + O = NO₂. 2. By heating LEAD NITRATE (NO₂)₂O₂Pb to strong redness in a retort $2[(NO_2)_2O_2Pb] = 2OPb + O_2 + 4NO_2$.

IV. Carbon C = 12.

A tetrad element, whose natural condition is that of a solid body. Native in two dissimilar, allotropic modifications. 1. As Diamond, sp. gr. 3.33 to 3.55. In forms belonging to the regular system. Insoluble in all media and infusible. The hardest of all bodies, cut and polished by its own powder. Lustrous and of high refractive power. A non-conductor of electricity. Heated in voltaie are, it swells up, resembles coke in appearance, and becomes a conductor of Electricity. 2. As Graphite or Plumbago of sp. gr. from 2.35 to 2.15. In powder known as black lead. Either massive, or in six-sided plates belonging to rhombohedral system: hence is Carbon dimorphous, as it crystallizes in two irreconcilable geometrical forms. Metallic lustre, friable, unetuous to the touch, and leaves black mark upon paper. Very hard. An excellent conductor of electricity. Used for protecting iron from rusting, and for lubricating machinery. When acted upon by nitrie acid and potassium chlorate, into GRAPHIC ACID C11H4O5; diamond, similarly treated, not acted upon. As amorphous Carbon or lamp-black, a third artificial variety of carbon must be mentioned. It is the basis of printing-inks, and is readily produced by the incomplete combustion of resinons bodies, rich in carbon and hydrogen. It may also be considered the light-giving principle in flames. Wood-charcoal, coke and soot, are also impure varieties of carbon. Strongly antiseptic: Cataplasma carbonis. Decolorizing. All amorphous varieties of carbon, when heated with nitrie aeid and potassium chlorate, are dissolved to brown solutions.

Compounds. Carbon with Hydrogen. 1. ACETYLENE, or ETHINE $C_2H_2 = 26$. Colorless gas of peculiar odor, burning with smoky flame to earbonic anhydride CO, and water OH2. Two vols., CaHo, requiring five vols. of O for complete combustion. Prep. A constituent of coal-gas, and always produced in the incomplete combustion of METHANE CH, and ETHENE C2H,. Also, by synthesis of its elements. 2. Methane $CH_4 = 16$. Also called marsh-gas, light carbonetted hydrogen and fire-damp. Colorless, inodorous, tasteless gas, scarcely soluble in water. Inflammable, burning into OH2 and CO2, requiring twice its volume of oxygen and 10 x its volume of air. Is the first of the paraffins, see 'Org. Chemistry.' As to quantity, is most largely present in coal-gas. Prep. by heating SODIUM ACETATE CH3COONa, with sodium hydroxide HONa; sodium carbonate CO,ONa), and METHANE CH4 are alone produced. [Excess of Cl2 in exposed light converts CH4 into CCl4 and 4HCl. Moist CH4 and 4Clo(+2OHo) in diffused light into CO2 + 8HCl.] 3. ETHENE C₂H₁ = 28. Also ethylene, and olefant gas. Colorless, transparent, of faint alliaceous odor. Liquefied under great pressure. Burns with white flame into CO2 and OH2. One vol. requires three vols. of **0** for complete combustion. $C_2H_4 + 3O_2$ $= 2CO_2 + 2OH_2$. Soluble in twelve times its bulk of water. Contained in coal-gas. Prep. a. From Ethine C2H2 by nascent hydrogen. $C_2H_2 + H_2 = \hat{C}_2H_4$. b. From ETHYLIC ALCOHOL C_2H_3OH , by a desiccator or dehydrant. $C_2H_3OH - OH_2 = C_2H_4$. [ETHENE C2H4 unites directly with Cl2 to ETHENE DICHLORIDE C2H1Cl2 or Dutch liquid. Colorless, aromatic liquid, of sp. gr. 1.28 at 0° C.] 4. BUTYLENE C.H. = 56. Also, Oil-gas. Colorless gas, liquid at oo C. Polymeric with ethone; the same percentage composition, with different condensation in the molecule. -Carbon with Oxygen. 1. CARBON OXIDE OF CARBONIC OXIDE CO = 28. Transparent colorless gas, of sp. gr. 0.967. 100 vols. of water dissolve 3.28 vols. at o° C., and 2.43 vols. at 15° C. Irrespirable; uninflammable. Burns with blue flame into CO. [Absorbed by K₂ at 80° C., and forms K₂C₂O₂. Solution of Cu,Cl, also absorbs it, and forms CO, Cu₂Cl₂, ²OH₂ in seales. As the residue of CO2 after abstraction of O, it constitutes an important dyad radicle, CARBONYL CO, in organic bodies. Contained in coal-gas, &e. Prep. a. By heating CO2 with C = 2CO. b. By heating zine or ferrum in CO_2 . $Zn + CO_2 = ZnO + CO$. c. By heating CO₂ and H₂ together: $= OH_2 + CO$. d. By

heating OXALIC ACID C2O2(OH)2 with a desiccator: = OH2 + $CO_2 + CO_2$. Carbonic anhydride, or carbon dioxide $CO_2 = 44$. Colorless, transparent gas, of faint acidnlons taste and smell. Sp. gr. 1.52. One hundred c.ii. weigh 47,445 grs. at 15°.5 C., and 30" bar. Very injurious to life, but less so than carbon oxide. At 15°.5 C. water dissolves its own measure of the gas, and an additional volume for each additional atmosphere. As it is fully burnt, it is of course uninflammable; employed as an extinguisher of combustion. Under a pressure of 38.5 atmospheres at o° C. into a colorless, limpid liquid, lighter than water; then into a snow-white solid by its own evaporation. It is contained in the air to the extent of 0.035 per cent.; in respired air to 3.5 per cent. Product of combistion of all bodies containing carbon, and a result of deeay, germination, fermentation, and putrefaction. Its salts are called CARBONATES. No known combination with water, but hypothetical CARBONIC ACID CO(OH)2 is a dibasic acid, containing two atoms of hydroxyl. Most carbonates are insoluble in water, and they all effervesce on the addition of most acids. Prep. a. By heating CALCIUM CARBONATE CO(O,Ca) or CaCO, to redness, it breaks up into CALCIUM OXIDE CaO and OARBONIC ANHYDRIDE CO., b. By burning C in $O_2 = \mathbf{CO}_2$. c. By adding hydrogen nitrate to calcium carbonate : Calcium nitrate [$(NO_2)_2O_2Ca$], water OH_2 and carbonic anhydride CO_2 result. Thus : $^2HNO_3 + CaCO_3$ = Ca2NO₃ + OH₂ + CO₂. CARBONIC ANHYDRIDE combines readily, and is therefore quickly absorbed by potassoxide or calcinm oxide, or their hydroxides: $e.g. OK_2 + CO_2 = CO(OK)_2$. $KOH + CO_2 = CO(OK)(OH)$. $CaO + CO_2 = CaO, CO_2$.

Carbon and Nitrogen. Cyanogen C2N2 = 52. Cyanogen is a colorless gas, of odor resembling peach-blossoms. Sp. gr. 1.8, or 26 when referred to H. Inflammable with color of peachblossoms into CO₂ and N₂. One vol. requires 2 vols. of O for complete combustion. At 7°.2 C., under pressure of 3.6 atmospheres into colorless liquid. Water dissolves 4 x its volume. Always produced as a eyanide when various metallic oxides are presented at a red-heat to N or to nitrogenized compounds. Prep. a. Heating MERCURIC CYANIDE HgC. N2: into Hg, CYANO-GEN C2N2 and PARA-CYANOGEN, a polymeric modification of cyanogen. b. Passing air over potassium earbonate mixed with chargoal and contained in a red-hot tube: $CO(OK)_2 + N_2 +$ 4C = 3CO + 2CNK. Then Potassium Cyanide CNK, with water and mercuric oxide OHg, gives potass-hydroxide and mercuric cyanide. Cyanogen, a good illustration of a radicle, or an unsaturated carbon residue. Carbon, a tetrad, united with triad NITROGEN, as Cyanogen, is a monad radicle. Hydrogen Cyanide CNH, is prussic acid, a mono-basic acid. A colorless, transparont liquid, very volatile, intensely poisonons: oppression and constriction of fanees. Ammonia and water, best antidotes. Vapor inflammable. One vol. CN and oue vol. of H united to 2 vols. in prussie acid. Potassium burns when heated in it, and displaces H. Prep. From potassium cyanide CNK by dilute sulphuric acid $SO_2(OH)_2$. Thus: $CNK + SO_2(OH)_2 = CNH + POTASSIUM HYDROGEN SULPHATE <math>SO_2OHOK$. See 'Organie Chemistry.'

V. Sulphur S = 32. $S_2 = 64$.

A dyad element, found native in Sicily and on the coasts of the Mediterranean. Pale-yellow, brittle, solid, of sp. gr. 2.045. Melts at 114°.5 C. into pale amber-eolored liquid. Insoluble in water. Crystallizes from solution in Carbonic sulphide CS. as octahedron with rhombic base; the form of native sulphur. IIt is also very soluble in Sulphur Dichloride SoClo. in Benzene C₆H₆, and boiling TURPENTINE C₁₀ H₁₆; little in ethyl aleohol C₂H₃OH, and still less in ether C₄H₁₀O, and in ehloroform CHCl3.] Heated beyond melting-point, darkens, thickens, and at 240° C., or so, is so tenacious that vessel may be upturned without loss. Then thin fluid again, and boils at 446° C. Sulphur sublimed; flowers of sulphur. Heated in air to 260° C. it burns with violet flame to SULPHUROUS ANHYDRIDE SO... Both allotropie and dimorphous. If native sulphur be melted and crystallized it separates in oblique prisms. Sp. gr. 1.98. Soluble in the same agents as the native. If either the native or prismatie variety (electro-negative) be heated to 250° C., or so, and poured into water, a third modification, the amorphous or ductile variety is obtained. Sp. gr. 1.957. Insoluble in all agents: electro-positive. Also a red and a black variety; the more frequently heated to 315° C., and eooled, the more of the black is obtained. Sulphur forms sulphides with the metals. IRON-PYRITES is Ferrous di-sulphide FeS₂. Magnetic pyrites Fe,S,. COBALT-GLANCE COSAS. NICKEL-GLANCE NISAS. ZINC-BLENDE ZnS. GREENOCKITE CdS. GALENA PbS. SILVER-GLANCE Ag.S. CINNABAR HgS. COPPER-PYRITES FeCus. GREY ANTI-MONY ORE OF ANTIMONY-GLANCE Sb₂S₃. ORPIMENT As₂S₃. REAL-GAR As₂S₂. Prep. a. Native by simple fusion from blue clay. Cast in moulds, as Tabland or prismatic Sulphur. b. Heating iron-pyrites in absence of air. ${}_{3}\text{FeS}_{2} = \text{Fe}_{3}\text{S}_{4} + \text{S}_{2}$.

N.B.—Vapor of sulphur anomalous. Molecular volume below 816° C., S_6 ; above 1040° C., S_2 ; as compared with air,

its vapor-volume is respectively 6.617 and 2.214.

Compounds. Of S with H. t. Hydrogen sulphide $SH_2 = 34$. Also sulphidetted hydrogen and rotten egg gas. Colorless gas, of offensive odor. Not irritant; narcotic. Sp. gr. 1.17. Water at 0° C., dissolves 4.37 times its volumo; at 15° C., 3.23

vols. Solution feebly acid, reddens litmus, and is an important test. When SH₂ heated with tin, same volume of hydrogen remains as of gas. Burns with blue flame into water OH₂ and sulphurous anhydride SO₂. Three vols of O required for complete combustion of SH₂. Blackens lead-paper. Under pressure of 17 atmospheres a liquid. Solid at -86° C., boils at -62° C. A constituent of Harrogate water. Emanates from sewers.

In acid solutions SH2 precipitates Pb, Cu, Cd, Hg, Ag, Au, Pt. Pd. Sb, As, Sn, and Bi, as sulphides. Thus: SO₂O₂Cd + $SH_2 + OH_2 = SO_2(OH)_2 + CdS_1OH_2$. Prep. of SH_2 . a. From FERROUS SULPHIDE SFe by dilute sulphuric acid SO2(OH)2. $\operatorname{FeS} + \operatorname{SO}_2(\operatorname{OH})_2 + n\operatorname{OH}_2 = \operatorname{SO}_2(\operatorname{O}_2\operatorname{Fc}) + \operatorname{SH}_2 + n\operatorname{OH}_2$. b. From ANTIMONOUS SULPHIDE SaSb, and Hydrogen Chloride ClH, we obtain Antimonous Chloride Clash and SHa. Thus: $S_2Sb_2 + 6ClH = 2Cl_3Sb + 3SH_2$. [Hydrogen persulphide S_2H_2 = 66. An oily liquid, of yellow color, analogous to O.H. Very unstable.] Sulphur and Oxygen. 1. Sulphurous anhydride or sulphur dioxide $SO_2 = 64$. Colorless gas, pungent, irrespirable, suffocating; ever formed when S is burnt in air. Employed in bleaching flaunel and straw, and as a disinfectant. Sp. gr. 2.21. 100 c.ii. weigh 68.69 grains. At -17°.8 C., liquid. Unites with OH, to SULPHUROUS ACID SO(OH), or H, SO3. Forms a hydrate SO(OH)2.70H2. Soluble in water. 100 measures take up 68.8 measures at oo, and 43.5 measures at 15°.5 C. Can be collected over mercury or by displacement. Decomposes SH.. Thus: $10S\dot{H}_2 = 2\dot{H}_2S_5\dot{O}_6 + 5S_2 + 8OH_2$. [Decomposes KMnO₄. Thus: ${}_{2}KMnO_{4} + {}_{5}SO_{2} + {}_{2}OH_{2} = \bar{K}_{2}SO_{4} +$ 2MnSO₄ + 2H₂SO₄.] Prep. a. Burning S in air or in O₂. b. Also by roasting iron-pyrites in air. $4\text{FeS}_2 + 11\text{O}_2 = 2\text{Fe}_2\text{O}_3$ + 880,. c. By boiling copper or mercury with sulphuric acid; mercuric sulphate, water, and sulphurous anhydride result. $Cu + 2SO_2(OH)_2 = SO_2O_3Cu + OH_2 + SO_3$. d. By heating charcoal with sulphuric acid. $C + 2[SO_2(OH)_2] =$ CO₂ + 2OH₂ + 2SO₂. Sulphites. Sulphurous acid dibasic. Alkaline sulphites soluble. Ordinary acids decompose them. Reducing agents. 2. Sulphuric anhydride SO₃ = 80. In white, silken needles. Sp. gr. 1,946. Melts at 18°.3 C., and boils at 35° C. Great affinity for water. Soluble in all-proportions in SO₂(OH)₂. It is contained in Nordhausen sulphuric acid, a brown fuming liquid of sp. gr. 1 9. SO, can be prepared by passing SO₂ + O through red-hot tube filled with spongy platinum. Generally by heating almost dry ferrous sulphate, which gives Nordhausen sulphuric acid SO3, SO2(OH)2, from which SO3 by gentle heat. Thus: $4(SO_4Fe) + H_2O = 2Fe_2O_3 + 2SO_2 +$ SO3, SO (OH)2. 3. Sulphuric acid or Hydrogen sulphate II2SO4, = 98 or OH₂, SO₃ or SO₂(OH)₂; the latter preferred, as it is a di-basic acid of first importance, and contains the dyad radicle So. "Oil of vitriol." Heavy liquid of sp. gr. 1.848. Solid at -26° C. Boils and distils at 338° C. Chars organic bodies; great desiccator and dehydrant. Great affinity for water, forming two hydrates. So (OH), HoO of sp. gr, 1.78, freezes at 8°.3 C., hence glacial sulphuric acid. SO₂(OH)₂, 2H₂O a further hydrate, of 1.62 sp. gr. Used in making SO_2 ; NO_2OH ; ClH; CO_2 , &e. Sulphates; all soluble except of Barium, Strontium, and Lead. SODIUM SULPHATE SO, Na, 100H2, is "Glauber salt." BARIUM SULPHATE SO, Ba is "Heavy spar." STRONTIUM SULPHATE SO₄Sr is "Celestine." Magnesium sulphate SO₄Mg,7OH, is "Epsom salt." ZINC SULPHATE SO, Zn, 7OH, is "Zinc vitriol." CUPRIC SULPHATE SO4Cu,5OH2 is "Blue vitriol" LEAD SUL-PHATE SO, Pb is "Lead vitriol.' Prep. of oil of vitriol SO, (OH). In leaden chambers. At the Felling works these are 280' long by 20' wide and 18' high. The essentials in the manufacture are: SO2: NO,OH: H2O and O2 from the air. Simplest intelligible changes may be thus stated. a. $SO_2 + 2(NO_2OH) = SO_2(OH)_2 + 2NO_2$. b. $SO_2 + NO_2 + H_2O = NO + SO_2(OH)_2$. c. $NO + O = NO_2$. Thus a limited supply of nitric acid changes an almost unlimited amount of SO, into SO₂(OH)₂. The acid on the floor is the second hydrate somewhat diluted. By evaporation in leaden pans, it becomes first hydrate; beyond this point the concentration is conducted in vessels of glass or platinum, till, by the further loss of water, we obtain oil of vitriol, boiling at 333°, when the operation is stopped. 4. Thiosulphuric acid SSO(OH)₂ = H₂S₂O₃ = 114. Unknown in free state, as on addition of an acid to one of its salts, it breaks up into $OH_2 + SO_2 + S$, which is precipitated. Formation of its sodium salt, by digesting solution of sodium sulphite SO(ONa). with S=SSO(ONa). Sodium thiosulphate SSO(ONa),5H,0 is the common hyposulphite of soda used in photography, and as antichlore for removing traces of chloring from bleached goods, Dry salt, heated in close vessels; 4Na₂S₂O₃=Na₂S₅ + 3Na₂SO₄. [5. Hyposulphurous acid S(OH)2 or H2SO2. Orange-yellow, rapidly decomposing. Zn dissolves in solution of sulphurous acid, and affords a yellow solution of zine hyposulphite. 6. Dithionic acid S₂O₄(OH)₂ or H₂S₂O₆ = 162. Is more stable. Its manganous salt, by passing SO₂ through MnO₂ suspended in water = S₂O₄O₅Mn. If temperature allowed to rise, we obtain SO₂O₂Mn. Dithionates all soluble. When heated with an acid, SO, evolved, but no S is deposited. On concentration of the acid, it breaks up into SO(OH), and SO,(OH), 7. Trithionic acid S₃O₄(OH)₂ or H₂S₃O₆, in prismatic crystals, easily decomposing into S, SO₂ and SO₂(OH)₂. Potassium salt, by potassium hydrogen sulphite with flowers of sulphur. 8. TETRATHIONIC ACID S₄O₄(OH)₂, readily breaks up, by boiling. into S2, SO2 and SO2(OH)2. 9. PENTATIHONIC ACID \$20,(OH)...

Unstable acid, prepared by passing a enrrent of SH_2 through a solution of sulphurous acid $SO(OH)_2$. Thus: $10SH_2 + 10SO(OH)_2$

 $= 5S_2 + 18OH_2 + 2S_5O_4(OH)_2$.

So then we have: Hyposulphurous acid $S(0H)_2$. Sulphurous acid $S0(0H)_2$. Sulphuric acid $S0_2(0H)_2$. Thicsulphuric acid $S0(0H)_2$, or sulphuric acid in which S displaces O. Dithionic acid $S_20_4(0H)_2$. Trithionic acid $S_20_4S(0H)_2$. Tetrathionic acid $S_20_4S_2(0H)_2$. Pentathionic acid $S_20_4S_3(0H)_2$. All dibasie, and containing two atoms of hydroxyle 0H.

Sulphur and Nitrogen. S₂N₂. Golden-yellow rhombs, insoluble in water. Explodes when heated to 157° C. Of faint odor and irritating. Obtained by passing dry NH₃ through solution

of S₂Cl₂ in carbonic sulphide CS₂.

Sulphur and Carbon. a. Carbonous sulphide CS = 44. A brown powder, of sp. gr. 1.66. Insoluble in water, benzene, alcohol and ether, slightly in carbonic sulphide. b. Carbonic sulphide CS₂=76. Transparent colorless liquid, of sp. gr. 1.272, of great refractive power. Boils at 83° C. Very inflammable, burns to CO₂ and SO₂. When pure (after long agitation with mereury) of ethereal odor: generally repulsive like cabbage water. Great solvent of sulphur, phosphorus, iodiue, caoutehoue, oils, &c. Unites with metallic sulphides to Sulphocarbonates. Prep. of CS₂. By passing the vapour of S over red-hot

charcoal contained in porcelain tube.

Sulphocarbonic acid $CS(HS)_2$ or H_2CS_3 , answers to the presence of sulphoxyl instead of hydroxyl: from the ammonium salt by dilute acid. When CS_2 is heated with water in a scaled tube, into CO_2 and H_2S . With nascent H_2 into CSH_2 and SH_2 . Exposed to light into CS and S which dissolves in CS_2 . [Carbon oxysulphide COS is a gas of sp. gr. 2.104. soluble in its own volume of water. Absorbed by potasshydroxide as readily as CO_2 , and liberated by weak acids. $Prep.\ a.$ by direct combination of CO with S in vapor, in passage through red-hot tube. b. gently heating SO_3 with $CS_2 = S + SO_2 + COS$. c. from hydrogen sulphoeyanate by water: $CNSH + OH_2 = NH_3 + COS.$]

[VI. Selenium Se = 79.5. Se₂ = 159.]

Selenium is a dyad element in hydrogen selenide. SeH₂. By Berzelius in 1817. Never native. Greatest analogy to sulphur. A reddish-brown solid, of imperfect metallic lustre, somewhat translucent. Sp. gr. 4.3. Melts above 100° C, and boils at 343° C. Insoluble in water and in alcohol; slightly in CS₂. Soluble in sulphuric acid. Many allotropic varieties; odor, as of decayed horseradish when heated in air. Selenium and Hydrogen. Hydrogen selenide SeH₂ = 81.5. Colorless,

inflammable gas, of very offensive odor. Soluble in water, and precipitates Scienides of metals. Se and 0. Scienious anhydride $SeO_2 = 111.5$. In snow-white needles. Either by burning Se in O or by nitric acid upon scienium. Selenious acid $SeO(OH)_2$, is readily reduced by $SO(OH)_2$, depositing Sc. Also by Zn or Fc. Alkaline scienites soluble. Selenic acid $SeO_2(OH)_2 = 145.5$. Resembles sulphuric acid. Prepared from lead scienate by SH_2 . Carbonic scienide CSe_2 . A pungent liquid resembling CS_2 .

[VII. Tellurium Te = 128. $Te_2 = 256$.

Rarely native in Hungary. Discovered by Mueller in 1782, and by Klaproth, in 1798, named Tellurium. Chiefly as telluride of silver, gold, copper, bismuth and lead. Analogous to sulphur aud selenium. Lustrous like silver; brittle. Rhombohedral crystals. Sp. gr. 6,26. Melts below red-heat. Bad conductor of heat and electricity. Burns when heated in O, with blue flame edged with green to TELLUROUS ANHYDRIDE TeO₂. Hydrogen telluride TeH₂ = 130. Gas, of sp. gr. 4.53. Burns with blue flame. Soluble in water; reddens litmus, and oxydizes slowly depositing tellurium. Two sulphides. TeS, and TeS. Tellurous anhydride TeO₂ = 160. Fuses easily. Yellow whilst hot. When tellurium is boiled with NO2OH, and then the solution poured into water, TELLUROUS ACID TeO(OH), is deposited as a bulky powder. By heat into OH2 and TeO2. TELLURIC ACID TeO2(OH)2,20H2 in stricted, 6-sided prisms. By oxydation of tellurium with potassium nitrate, potassium tellurate is obtained. Whether as tellurite or tellurate, tellurium is thrown down from its solutions by Zn or Fe. Tellurates of alkaline metals reduced by Charcoal at a red-heat to tellurides.]

VIII. Chlorine Cl = 35.5. $Cl_2 = 71$.

Not native. Discovered by Scheele in 1774. Oceurring in various chlorides. As potassium, sodium, calcium and magnesium chlorides in sca-water. Monad element, discovered by Scheele in 1774. Yellowish-green, χλωρδε, gas, uninflammable, irrespirable, suffocating. (Autidotes: weak ammonia, and dilute alcohol.) Sp. gr. 2.47. 100 e.ii. weigh 76.3 grains. Under pressure of 4 atmospheres at 15°.5 C., a yellow liquid of sp. gr. 1.33. Water dissolves 2.37 times its vol. at 15° C. Aqua chlorata. It also unites with water at 0° to a solid hydrate Cl₂100H₂. In presence of light, Chlorine decomposes water, with separation of oxygen. Its affinity for H and other

metals is very great. Many metals take fire in Cl gas: nearly all are tarnished, therefore Cl cannot be collected over mercury. Chlorides formed. Cl bleaches and disinfects: it decomposes at once many Hydrogen compounds. Thus: ${}_{2}\text{Cl}_{2} + {}_{2}\text{SH}_{2} =$ HCl + S_2 . Again, in light: ${}^2OH_2 + {}^2Cl_2 = {}^4ClH + {}^0Q_2$. Hence also an oxydizing agent. Thus: $Cl_2 + SO_2 + {}^2OH_2 =$ 2ClH + SO (OH). All CHLORIDES soluble in water, except of SILVER ClAg, and LEAD Cl2Pb. Prep. of Chlorine. a. by action of chloride of hydrogen ClH, upon manganese dioxide MnO2. Thus: MnO₂ + 4ClH = Manganous chloride Cl₂Mn + water 2OH₂ + CHLORINE Cl₂. b. by Weldon's process. MANGANOUS CHLORIDE MnCl., is precipitated by hot milk of lime or magnesia, and a stream of hot air blown through. First, manganous hydroxide is precipitated, and this with O from hot air converts manganous hydroxide into MANGANESE DIOXIDE MnO, united with the CALCIUM OXIDE CaO, or MAGNESIUM OXIDE MgO as CaO,MnO2 or MgO,MnO2. When heated with hydrogen chloride, MAGNESIUM CHLORIDE MgCl, or CALCIUM CHLORIDE CaCl2, together with WATER, are formed, and the further action as described above between MnO₂ + 4ClH = Cl₂Mn + 2OH₂ + Cl₂. c. Deacon's process. By passing a mixture of hydrogen chloride and air over enprie snlphate heated to 370°-340° C. The action of the metallic salt one of contact-actions. d. From SODIUM CHLORIDE NaCl, MANGANESE DIOXIDE MnO2 and SUL-PHURIC ACID SO, (OH). MANGANOUS SULPHATE SO2O2Mn. sodium sulphate SO2(ONa)2, WATER OH2, and CHLORINE Cl2 result. Thus: $MnO_2 + 2NaCl + 2SO_2(OH)_2 = SO_2(O_2Mn) +$ SO₂(ONa), + 2OH₂ + Cl₂. Compounds. Cl with H. Hydrogen chloride ClH. Hydrochloric acid or muriatie acid. ClH = 36.5. Colorless, pungent, incombustible gas, of sp. gr. 1.269. 100 e.ii. weigh 39.23 grains at 15°.5 C. Intensely acid taste. Under pressure of 40 atmospheres at 10° C., a colorless liquid. By condensing moisture, fumes in air. Very soluble in water, which at oo C, takes up 500, and at 10° C. 472 times its vol. The solution in water long known. Sp. gr. of solution 1.22, is colorless, fuming, with 44 per cent. of the gas, answering to ClH, 3OII. No real hydrate. When heated, ClH is given off, sp. gr. sinks to 1,11, contains about 20 per cent. of the gas and may be distilled. This acid corresponds to ClH, 80H,, but is no true hydrate. The only true hydrate ClH, 2OH2, obtainable in crystals at low temperatures. Common muriatic acid is yellow from the presence of ferrie ehloride, and also contains sulplurie acid. The pure solution leaves no residue upon Silver nitrate NO2OAg gives with Cl, ClH and other soluble ehlorides a white curd-like precipitate of SILVER CHLORIDE AgCl, insoluble in NO, OH, soluble in NH3. Prep. of CIH. 1. By union of Cl and H, in equal volumes, in sunlight

or by a light. $\text{Cl}_2 + \text{H}_2 = 2\text{ClH}$, 2. From sodium chloride CINa by SULPHURIC ACID SO₂(OH)₂: CINa + SO₂(OH)₂ = SO₂OHONa + ClH. Action of ClH upon METALS. Upon monads. $K_2 + 2\text{ClH} = 2\text{ClK} + H_2$. Upon a dyad. Mg + 2ClH = Cl₂Mg + H₂. Upon monad-oxides. $K_2\text{O} + 2\text{ClH} = 2\text{KCl} + \text{H}_2\text{O}$. Upon dyad-oxides. ZnO + 2ClH = ZnCl₂ + H₂. Upon triad-oxides. $Fe_2O_3 + 6HCl = Fc_2Cl_6 + 3H_2O$. Upon tetrad-oxides. $SnO_2 + 4ClH = SnCl_4 + 2H_2O$. Action of HCl upon hydrates. $KOH + HCl = KCl + \tilde{H}_2O$. BaO,OH₂ + $2HCl = BaCl_2 + 2OH_2$. $Fe_2O_{33}OH_2 + 6ClH = Fe_2Cl_6 + 6OH_2$. Upon Peroxides like MnO.; PbO.,—not basic. 4ClH + MnO. = 2OH₂ + MnCl₂ + Cl₂. Aqua regia or nitro-muriatic acid is a mixture of HCl with NO,OH, evolving Cl., a great solvent of gold, platinum, &c., chlorides of which are thus obtained. Chloro-nitric gas NOCl₂, formed same time. 6ClH + 2NO₂OH = $2 \text{NOCl}_2 + 4 \text{OH}_2 + \text{Cl}_2$. Only $\frac{1}{3}$ of the Cl obtained. In chloro-nitric gas, Cl2 takes the place of O in NO2. Lemonyellow gas, forming red, fuming fluid below -7° C. Chloronitrous gas NOCl, by mixing NO with Cl, condensed into two vols. Compounds of Cl with O. a. Hypochlorous anhydride $OCl_2 = 87$. Gas of pale-yellow color, analogous to OH_2 . Condensable into deep-red liquid. Prep. from mercuric oxide, by action of Cl2. MERCURIC OXY-CHLORIDE HgO, HgCl2 and $0Cl_2$ result. Thus: $2OHg + 2Cl_2 = OHg, Cl_2Hg + 0Cl_2$. One vol. of water absorbs 200 vols. of OCl2, and forms Hypochlorous acid ClOH. Yellow color, acid, and sweetish smell. Great bleaching agent. Decomposed by ClH. Thus: ClOH + ClH = OH₂ + Cl₂. Hypochlorites. Prep. a. by passing Cl₂ through hydroxides at low temperatures. 2 HOK + Cl₂ = ClK + ClOK + OH2. b. by saturating ClOH with the respective metallic oxide. c. by distilling CALCIUM HYPOCHLORITE Ca(OCl)₂, with dilute sulphuric acid. 2Ca(OCl)₂ + SO₂(OH)₂ = Cl₂Ca + SO₂O₂Ca + 2CloH. d. passing Cl₂ into water in which, say, calcium carbonate CO(O₂Ca) is diffused. 2Cl₂ + OH₂ + CO₃Ca, = CO₂ +Cl₂Ca + 2CloH. Chloride of lime is bleaching powder. Consists mainly of CALCIUM OXY-CHLORIDE Cl. OCa mixed with unaltered CALCIUM HYDROXIDE (OH)2Ca. According to Kolb, it consists of Ca3H6O6Cl4, and is decomposed by water into CALCIUM HYPOCHLORITE Cl2OCa, CALCIUM CHLORIDE Cl2Ca. CAL-CIUM HYDROXIDE (OH), Ca + 2OH2. The dry chloride of lime gives up no CALCIUM CHLORIDE Cl2Ca to alcohol: hence not contained, but produced by water. HCl can be changed into HOCl by nascent oxygen, derivable from KMnO4. [b. Chlorous anhydride $Cl_2O_3 = 119$. Or $O(OCl)_2$. Gas of deep greenishyellow color, condensable to deep-brown mobile liquid. Water dissolves 10 × its volume. Dangerous compound. Prep. action of hydrogen nitrite NO(OH) upon Potassium chlorate

Cloo(OK). Thus: $2NOOH + 2Cloo(OK) = 2NO_{\circ}OK + OH_{\circ}$ + O(OCl)2. With water forms CHLOROUS ACID OCl(OH) or HClO... Addition of As, O3 + NO, OH to chlorites does not destroy their bleaching powers, as it does those of hypoehlorites. c. Chlorine peroxide, or dioxide ClO₂ = 67.5. Gas, of very deep yellowish-green color; at -20° C. a red fluid. Water dissolves 20 times its bulk. Explodes above 60° C. Must be collected by displacement. Prep. by action of SULPHURIC ACID (3) upon POTAS-SIUM CHLORATE (2) = $2\text{ClO}_2 + \text{KClO}_4 + \text{OH}_2 + 2(\text{SO}_2\text{OKOH})$. d. Chloric acid Clo20H = 84.5. Anhydride unknown. Syrnpy liquid of faint chlorous odor. Very acid. Decomposed by organie matters. Monobasie. Easily prepared from BARIUM CHLORATE Ba2ClO3, by dilute sulphurie acid. All chlorates soluble in water. When Cl₂ is passed into potassium hydroxide, and the temperature allowed to rise, water, chloride and chlorate of potassinm result. $6HOK + 3Cl_2 = 3OH_2 + 5ClK + ClO_2OK$. When ehlorate of potassium is heated to 370° C., it fuses, and is converted into potassium chloride KCl and O, by sufficient heat. SO₂(OH)₂ evolves ClO₂ with its peculiar odor, evolves etchlorine, a yellow explosive gas consisting of 2Cl2Os. CloO2. [e. PERCHLORIC ACID ClO30H = 100.5. Colorless volatile liquid, and most powerful oxydizing agent. A hydrate HClO, OH, in white crystals. Perchlorates. Mostly deliqueseent; all soluble. Potassium perehlorate with difficulty. All decomposed by heat into chlorides and oxygen. Clo. OK easily prepared from ClO₂OK by stopping the evolution of O₂ when 1 has passed over in the making of that gas. 2ClO2OK = ClK + O₂ + ClO₃OK. As ClO₃OK readily separated by crystallization from the very soluble ehloride, PERCHLORIC ACID CIO, OH is made by distilling the potassium salt with sulphuric acid.] [Cl with N. Nitrogen chloride NCl3? Obtained indirectly. Oily liquid of sp. gr. 1.653. Most dangerous compound. Explodes spontaneously below 100° C. Prep. by action of Cl npon ammonium chloride NH₄Cl + 3Cl₂ = 4ClH + NCl₃.] Cl with C. C₂Cl₂, C₂Cl₄, C₂Cl₆ and CCl₄. 'Organic Chemistry.' Carbonic oxy-chloride COCl2, is the phosgene gas of Davy. Carbon monoxide CO, unites in sunlight directly with Cl., volume for volume. Pungent, suffocating gas. Liquid at oo C. Very interesting compound. [Cl and S. Sulphur chloride S2Cl2 = 135. Yellow, volatile liquid of sp. gr. 1.68. Disagreeable, pungent odor. By passing dry Cl, into melted sulphur, and digestion upon sulphur. Slowly decomposed by water. Sulphur dichloride SCl₂ = 103. Deep red, furning liquid, boiling at 164° C. Produced by saturating S2Cl2 with Cl2. Sulphur tetrachloride SCl₄ by saturating the ehloride with Cl_2 at -20° C. Oxychlorides. SOCl, and SO, Cl.,]

IX. Bromine Br = 80. $Br_2 = 160$.

Monad element, never native. Discovered by Balard in 1826. Closely allied to chlorine. Contained as magnesium and sodium bromide in sea-water, and largely in a spring at Kreuznach. Intensely red liquid, very volatile; freezes at -24°.5°C., and boils at 63°C. Sp. gr. 2.976. Vapor intensely irritating, reminding of chlorine. Little soluble in water, more in alcohol, very soluble in ether. Hydrate Br2,100H2. NO2OH does not dissolve BrAg, and the latter, of yellowish color, is with difficulty soluble in NH₃. Otherwise bromides resemble chlorides. $\check{P}rep.$ of \mathbf{Br}_2 . $\check{\mathrm{MgBr}}_2 + \mathrm{Cl}_2 = \mathrm{MgCl}_2 + \mathrm{Br}_2$. bromine dissolved in ether, and treated with KOH. 3Br2+6KOH = 5KBr + KBrO₃ + 3OH₂. By heat 2KBrO₃ = 2KBr + 3O₂. Then: ${}_{2}KBr + MnO_{2} + {}_{3}SO_{2}(OH)_{2} = SO_{2}(O_{2}Mn) + {}_{2}(SO_{2}OKOH)$ +20II2+Br2. Compounds. Br with H. Hydrogen bromide, or hydro-bromie acid BrH = 81. Colorless gas. Its solution in water is a true hydrate BrH,50H2, a colorless fuming liquid of sp. gr. 1.486. Boils at 126° C., and distils. Oxydizes only in part on exposure to air. Solution decomposed by Cl2. 2HBr $+ Cl_2 = 2ClH + Br_2$. Forms bromides and water, by contact with metallic oxides and hydroxides. Prep. a. By passing a stream of SII, through Br₂ diffused through water. 2Br₂ + 2SII₂ $=S_2 + 4BrH$, b. Bringing phosphorous bromide into contact with water, and distilling. $PBr_3 + 3OH_2 = PHO(OH)_2 + 3BrH$. c. Decomposing potassium bromide KBr with hydrogen orthophosphate $PO(OH)_3$. ${}_3KBr + PO(OH)_3 = PO(OK)_3 + {}_3BrH$. Br with 0. [HYPOBROMOUS ACID BrOH. Unstable. Formed by agitating HgO with Br₂ and water.] Bromic Acid BrO₂0H = 129. Resembles hydrogen chlorate. Best prepared from silver bromate by Br. Bromates: when heated, into O, and bromides. Per-BROMIC ACID BrO30H. An oily liquid, made by the action of Br₂ upon hydrogen perchlorate. It resists the reducing action of SH2 and SO2. [Br and N. Nitrogen bromide NBr3, oily liquid. Carbonic oxy-bromide COBr2. Br and S. S2Br2 and SBr2, are brown-red liquids.]

X. Iodine I = 127. $I_2 = 254$.

Monad element, not found native. Discovered by Courtois in 1811 in kelp, the ash of sea-weeds. Occurs as sodium iodido in sea-water; also in various springs. Silver iodide AgI is one of the rarer silver ores. Iodine obtained by sublimation resembles black lead, and erystallizes as oetahedron with rhombic base. Sp. gr. of vapour 8.716. Melts at 107° C., and boils at 175° C., the vapor possessing a deep violet, ιώδης, color. Sp. gr. of iodine 4.95. Very little soluble in water, but easily in alcohol: tineture of iodine. Stains the skin yellow. An energetic medicine. Cl, sets I2 free from its soluble salts, and I2 imparts a rich amethyst color to CS2: a test. Free iodine forms blue compound with starch: also a test. Iodides. Potassium iodide KI, much used in medicine. $2KI + 4NO_2OH = 2NO_2OK + 2NO_2OK$ +2OH₂+I₂. Prep. from sodium iodide NaI, in kelp, by SO₄H₂ and MnO₂, as in the making of Cl₂. Thus: 2NaI + MnO₂ $+3SO_2(OH)_2 = 2[SO_2(OH)(ONa)] + [SO_2(O_2Mn)] + 2OH_2 + I_2.$ Compounds. H with I. [Hydrogen iodide IH = 128. Colorless gas, fuming in air, of sp. gr. 4.44. Very acid and irritating. Compressible to a liquid, and even solid at -51°C. Very soluble in water: hydriodic acid. 2IH, 110H2 is the hydrate. Browns rapidly owing to oxydation of H₂. Decomposed by Cl₂, Br₂, NO₂OH. Dissolves Zn and Fe, evolving H₂. Prep. a. By heating I, in H2. b. By passing SH2 into H2O, admixed with I_2 . Thus: $2SH_2 + 2I_2 = S_2 + 4IH$. c. By phosphorous iodide and H_2O . $PI_3 + 3H_2O = PHO(OH)_2 + 3HI$. d. 8KI $+ P_4 + 10I_2 + 16OH_2 = 4[PO(OH)(OK)_2] + 28HI.]$ I with 0. [Two anhydrides and two acids. I203 and I205: with OH2 IO2,0H and 10,0H. a. Iodic acid 10,0H. Colorless, 6-sided tables, very soluble in water. Decomposed by morphia, iodine set free: a test for morphia. Heated to 107° C. into OH, and anhydride I_2O_5 . ${}_2IO_3H = OH_2 + I_2O_5$. Iodates: by heat into iodides and oxygen. Prep. of IO_2OH . a. By excess of Cl_2 upon I diffused through water; $I_2 + 5Cl_2 + 6OH_2 = 10ClH + 210_2OH$. b. $5ICl_3$ + SODIUM CARBONATE 9 CO(ONa)2 = 15 NaCl + 9CO2 + I2 + 3IO2Na. A mixture of hydriodic and iodic acids instantly decompose one another: $5IH + IO_2OH = 3OH_2 + 3I_3$. b. Per-iodic acid IO, H or IO, OH. In deliquescent oblique prisms containing OH. Melts at 130°, then into OH, and per-iodic anhydride I_2O_7 ; then evolves O_2 and changed into I_2O_5 , and finally into $I_2 + O_2$. Periodates. Prep. $IO_2 ONa + OI_2 + 3NaOH = 2NaOI$ + NaO, I, NaOH, OH2, the latter a sparingly soluble compound.] I and N. [Nitrogen iodide NHI, and NI, Black insoluble powder, explosive, dangerous. Prep. Precipitation of alcoholic solution of iodine by ammonia. ${}_{3}NH_{3} + {}_{2}I_{2} = {}_{2}NH_{4}I$ + NHI_2 . Decomposed by SH_2 . $NHI_2 + 2SH_2 = NH_4I + S_2$ + IH.] I and S. S. I. crystalline, brittle, steel-grey solid.

XI. Fluorine F = 19. $F_2 = 38$.

Monad element, never native. Supposed to be a colorless gas, when prepared by the action of iodine upon silver fluoride AgF. Two chief fluorides found native are: Calcium fluoride CaF₂, or Fluorspar, and Sodium aluminum fluoride 3NaF,AlF₃ or Cryolite. Compounds. F with H. Hydrogen fluoride or Hydrofluoric Acid FH = 20. Colorless, mobile liquid of

sp. gr. 0.988, which boils at 19°.4°C. Fuming, highly corrosive. Dangerous. The acid of sp. gr. 1.15 is a hydrate FH, 20H,.. boils at 120° C. Etches glass, owing to Fluorine forming with Silieon a volatile gaseous compound, silicon fluoride SiF4. Thus: $SiO_2 + 4FH = 2OH_2 + SiF_4$. Prep. of HF. CALCIUM FLUORIDE is distilled with SULPHURIC ACID in vessels of lead or silver, and the acid is received and preserved in vessels of lead, silver, platinum, or gutta-percha. $F_2Ca + SO_2(OH)_2 = SO_2(O_2Ca) +$ FH.

XII. Boron B = 11. $B_2 = 22$.

A triad element, never native. Contained in Borax. Alway: in combination with oxygen. By Gay-Lussac and Thénard in 1808. Amorphous boron, a dull-greenish powder, which soils the fingers, and is slightly soluble in water. NO2OH attacks and dissolves it as boracie acid. It burns vividly into BORACIC ANHYDRIDE B₂O₃, when heated in oxygen. Prep. by heating potassium boro-fluoride KF,BF, with the metal potassium in a small iron vessel, and removal of the soluble Potassium fluoride by water. ${}_{2}$ [KF,BF $_{3}$] + ${}_{3}$ K $_{2}$ = 8KF + B_{2} . There is also a erystalline variety of boron. Nearly colorless or brown, sp. gr. 2.63. Always contains Aluminum Boride B2Al. Very hard: scratches the ruby. Acids have no action upon it. Infusible, and only partially combustible in oxy-hydrogen. Prep. by dissolving amorphous boron in fused aluminum at a high temperature, and removal of aluminum by hydrogen chloride. Compounds. B and Boracic anhydride B₂O₃, = 70. Issues as boracic acid BO(OH).H2O with jets of steam in the maremma of Tuseany. Fuses to transparent glass, which remains clear on cooling. Prep. by heating boracic acid to redness. Volatilized with great difficulty, hence it drives out many salt-radicles when heated with their salts. Boracic acid BO(OH), OH2 or HBO2, OH2. In pearly seales, soluble in 25 parts of water at 18° C., and in 3 parts of boiling water. Turns turmeric paper brown. Soluble in alcohol and gives green color to flame. Borates are its salts: all soluble in NO,OH. Chief salt: BORAX or SODIUM BI-BORATE Na_2O , $2B_2O_3$ or $Na_2B_4O_7$, $1\circ OH_2$, which is found native. Dissolved in water, it is decomposed by dilute sulphurie acid, and furnishes boracic acid. B and N. [Boron nitride BN = 25. White amorphous powder, insoluble in water. In current of steam, yields NH3 + B2O3. Obtained by heating B in N. or better, borax with ammonium chloride. Na2O,2B2O3 + 2NH4Cl B₂O₃ + 2NaCl + 4H₂O + 2BN.] B and Cl. [Boron chloride BCl₃ - 117.5. Colorless, mobile liquid, of sp. gr. 1.35, boiling at 13° C. Decomposed by water into boracic and hydrochloric

acids: hence fumes in air. Prep. by heating mixture of B2O3

and charcoal to bright redness, and passing a stream of dry Chlorine over it.] **B** and **F**. [Boron fluoride $BF_3 = 6z$. A colorless gas, irritating, fuming. Water dissolves 700 times its volume, producing a fuming liquid of sp. gr. 1.77. The elements of water make it into B_2O_3 .6HF, really the character of the solution. Prep. of BF_3 . By igniting a mixture of ealeium fluoride with boracic anhydride. $5CaF_2 + 4B_2O_3 = 3Ca_2BO_2 + 2BF_3$. When BF_3 , dissolved in much water, fluoboric acid HF_3BF_3 , is obtained with free boracic acid. $8BF_3 + 6OH_2 = 2(BO_2H,OH_2) + 6(HF_3BF_3)$. Boron made from POTASSIUM BOROFILUORIDE KF_3BF_3, by heating with K.]

XIII. Silicon Si = 28.

Tetrad element, never native, Discovered by Berzelius in 1823. Combined with oxygen, silieon forms siliea or silieie anhydride, one of the most abundant minerals. Like boron, two distinct modifications of silicon are known, a. Amorphous silicon. Brown powder, insoluble in, and denser than, water. A nonconductor of electricity. Soils the fingers. Intact in nitrie or sulphurie acids: readily removed as gaseous Silicon fluoride by Hydrogen fluoride. Burns brilliantly when heated in air. Prep. by heating Potassium with Potassium silico-fluoride: 2(KF,SiF, + 4K₂ = 10KF + Si₂, b. Crystalline silicon. Steel-grey, metalline, and a conductor of electricity. Sp. gr. 2.49. Not attacked when fused with NO,OK or ClO,OK. Heated in Cl2, into SiCl4; in a stream of ClH into Silicon-chloroform SiHCl3 and hydrogen. Prep, by heating in a red-hot erueible a mixture of potassium silieo-fluoride, sodium and granulated zine: the liberated Si dissolves in the zine. The latter is removed by ClH. Compounds. Si and H. [Silicon hydride $SiH_4 = 32$. Colorless gas, which only takes fire spontaneously in air when free H is present. Passed through a red-hot tube, it is decomposed into Si and 2H₂. Impure it is obtained from magnesium silicide and ClH; always accompanied by free H.] Si and O. Silicic anhydride or Silica $SiO_2 = 60$. In two modifications, crystalline and amorphous. As "rock-erystal," in 6-sided, transversely striated prisms, terminated by 6-sided pyramids. Sp. gr. 2.69. Insoluble in water, and in all acids, except hydrogen fluoride, which volatilizes the silicon as fluoride Amethyst, earngorm, agate, flint, earnelian, onyx, chalcedony, are varieties more or less pure of quartz, or sitiea. Opal contains about 10 per cent of water. Fusible in oxyhydrogen. Amorphous siliea is a fine, white, tasteless powder, obtainable from either of the hydrogen silieates by a gentle heat. When once heated to redness, FH is its only solvent, by decomposition. Composition of the hydrates of siliea doubtful. 0H2,3SiO2 and 0H2,4SiO2. Silicates. Clay, felspar, mica, &c.,

are silicates. Metasilicates represented by formula H₂SiO₃ or Si0(0H)2; orthosilicates, by H.SiO4 or Si(0H)4. Hydrates of silica are soluble in water. At a red-heat SiO2 is one of the most powerful of the acids, as it is not volatile, and takes the place of the volatile salt-radicles in their respective salts. Potassium sulphate and silica strongly beated give potassium silicate as the residue. Glass is generally a mixture of certain silicates (see GLASS). Si and N. | Silicon nitride formed by heating Si in N. A light bluish fibrous compound.] Si and S. [Silicon sulphide Sis, White, earthy, solid; deliquescent. Decomposed by water into 2SH2 and SiO2. By heating Si in S vapor, SiS2 is formed.] Si and Cl. Silicon chloride SiCl, = 170. Transparent, colorless liquid, pungent, irritating. Sp. gr. 1.523. Decomposed by water into ORTHOSILICIC ACID Si(OH),, and 4HCl. Prep. by strongly heating a mixture of silica and charcoal, and passing a stream of Cl_2 over it: $SiO_2 + 2Cl_2 + C_2 = 2CO + SiCl_4$. Siliconchloroform SiHCl, mixed with SiCl, constitutes CHLORO-LEUKON Si₃H₄Cl₁₀. Si and Br. [Silicon bromide SiBr₄. A liquid of sp. gr. 2.813. Similarly prepared and of similar behavior to SiCl.] Si and I. [Silicon iodide SiI4. In colorless, transparent octahedra, which melt at 120°.5 C. From Si and I at high temperatures. Also Silicon sesqui-iodide Si₂I₆.] Si and F. Silicon fluoride SiF₄ = 104. Colorless gas of sp. gr. 3.6, funing strongly in moist air. Uninflaminable. Condensable to a liquid, which is solid at -140° C. Must be collected over water, as it is in part decomposed by the latter. Prep. heating CALCIUM FLUORIDE CaF2, together with SILICA SiO2 and SULPHURIC ACID in a dry flask, and collecting over mercury. 2CaF2 + 2SO2(OH)2 Then: $4HF + SiO_2 = 2OH_2 + SiF_4$. $= 2SO_{o}O_{o}Ca + 4HF.$ Hydrogen silico-fluoride 2HF,SiF, = 144. A sour, fuming liquid. If it attacks glass, it is because SiF4 volatilizes from it, and leaves HF. Action of water upon SILICON FLUORIDE SiF_4 . $3SiF_4 + 4OH_2 = Si(OH)_4 + 2[2HF,SiF_4]$ Orthosilicic acid can be removed by filtration, and is thus easily obtained pure.

XIV. Phosphorus P = 31. $P_4 = 124$.

A triad element, never native. A constituent of the bones of vertebrata, of blood and urine, &c. In primitive and volcanic rocks, in an oxydized form. Discovered by Brandt in 1669. Called Phosphorus from its luminosity in air (from \$\phi \text{as}\$ light, \$\phi \text{op}\phi \text{bearer}\$). Phosphorus is a translucent body, resembling wax, and, from oxydation, with a garlie smell. Brittle at low temperatures, it may be cut with a knife. Sp. gr. 1.83. Melts at 44° C., to a transparent liquid; boils at 208° C. 100 e.ii. of the vapor weigh 135 grains. It is insoluble in water, slightly

soluble in ether, but more so in benzene, turpentine and other oils. In CS2, in S2Cl2 and in PCl, it is freely solnble and may be obtained crystallized in rhombic dodecahedra. It is a noneonductor of electricity. When slowly oxydized, it gives rise to PHOSPHOROUS ANHYDRIDE P2O3: in active, full combustion, to PHOSPHORIO ANHYDRIDE P2O5. If one volume of H encloses one atom, one volume of phosphorns in vapor encloses two atoms: the molecules, of two volumes, therefore, four atoms. 11.19 litres weigh 62 grammes. Phosphorns affords one of the most interesting illustrations of allotropism.—If common or vitreons phosphorus be exposed to light under water, it becomes white, opake, less fusible and of sp. gr. 1.515; it is re-converted into the vitreous at a temperature below 50° C.—A third variety is obtained by suddenly eooling melted phosphorus. This is black and opake, but becomes vitreous by simple fusion and slow cooling.—A fourth, or viscous variety, by heating very pure phosphorus to near its boiling-point and suddenly cooling.—The fifth is the most important variety, as it is not poisonons, and need not be kept under water, as it does not inflame below 260° C. First obtained by sublimation of Phosphorns in the Torrieellian vacuum by exposure to sunlight. It is now largely prepared by heating vitreous phosphorns in an atmosphere of earbonic anhydride for 30 or 40 hours at a temperature of 230°C. to 240° C. A red powder of sp. gr. 2.14. Insoluble in all media. Crystallizes in rhombohedra. At 260° C. inflames and bnrns to P₂O₅. In Cl₂ it burns, as does the vitreous, and it detonates when rubbed with ClO,OK. Used in Bryant and May's, and Bell and Black's matches. Prep. of common phosphorus. Cal-CIUM ORTHO-PHOSPHATE (PO₄), Ca₃ is changed by SO₄H₂ into CALCIUM SUPERPHOSPHATE [(PO4)2H4Ca] and CALCIUM SULPHATE SO_4Ca . Thus: $(PO_4)_2Ca_3 + 2SO_4H_2 = 2SO_4Ca + (PO_4)_2H_4Ca$. The superphosphate is filtered off from the nearly insoluble SO₄Ca, is mixed with charcoal, dried, and heated to redness. The superphosphate (PO₄)₂H₄Ca by loss of 2OH₂ becomes CALCIUM METAPHOSPHATE (PO₃)₂Ca. And this metaphosphate heated to whiteness in an earthen retort with chargoal, gives ealeium pyrophosphate, earbon oxide and Phosphorns. Thus: $4[(PO_3)_2Ca] + 10C = 2[P_2O_2Ca_2] + 10CO + P_4$. The phosphorus is received in water. Compounds. P with H. Three compounds H_3P ; H_4P_2 and H_2P_4 , a gas, a liquid, and a solid. a. Phosphorus hydride or Phosphine $H_3P = 34$. Colorless gas of strong garlie odor. Very inflammable, burning into water and phosphoric anbydride. 4 vols. require 8 vols. of O for complete eombustion. Very little soluble in water. Behaves like ammonia and unites with IH to lodide of phosphonium H4PI. Prep. a. distilling Phosphorous ACID PHO(OH)2. Thus: $_4\text{PHO(OH)}_2 = _3\text{PO(OH)}_3 + \mathbf{H}_3\mathbf{P}_2 - b$. boiling phosphorus with

a solution of potassium hydroxide. $P_4 + 3KOH + 3OH_2 =$ 3PH₂O(OK) + H₂P. N.B.—In this process, the presence of liquid H₁P₂, renders phosphine spontaneously inflammable. Can be separated by a freezing mixture. Calcium hydroxide may also be used, and calcium hypophosphite obtained at same time $_{2}P_{1} + _{3}Ca(OH)_{2} + _{6}OH_{0} = _{3}P_{0}O_{0}H_{4}O_{0}Ca + _{2}H_{3}P$. [H₃P reduces silver-salts, $H_3P + 4OH_2 + 8NO_3Ag = 4Ag_2 + 8NO_2OH + PO$ (OH)3. Precipitates cupric phosphide 2H3P+3SO4Cu=3SO4H2 + Cu₃P₂. With IH, H₃P unites to form a erystalline compound PH,I, an iodide of phosphonium. P and O. Two anhydrides: P2O3 and P2O5, forming phosphites and phosphates of hydrogen and other metals. 1. [Hypophosphorous acid PH20 (OH), a syrupy liquid, apt to absorb oxygen, and therefore a deoxydizing agent. Immediately reduces potassium permanganate. Hypophosphites all soluble. By heat into orthophosphoric acid PO(OH), and phosphine H,P. From barium hypophosphite by dilute sulphurie acid, we obtain the acid or hydroxyl salt. 7 2. Phosphorous anhydride P.O. = 110. White powder, volatile, deliquescent, inflammable. By slow combustion of phosphorus in dry air. Phosphorous acid or hydrogen phosphite PHO(OH)₂. Crystalline deliquescent substance prone to further oxydation. Phosphites, neutral and acid, as di-basie. [In a free state does not immediately reduce potassium permanganate. Reduces sulphurous acid to hydrogen sulphide with deposit of S by reaction upon the SO(OH), and raises itself to orthophosphoric acid.] Prep. by adding water to phosphorous elloride, and removal of hydrogen elloride by heat. Thus: $PCl_3 + 3OH_2 = 3ClH + PHO(OH)_2$. 3. Phosphoric anhydride Po05 = 142. Snow-white, flocculont, deliquescent powder, fusible and volatile at a white heat. Great affinity for water; powerful desiceator, surpassing all others. Forms with water three acids or salts of hydrogen, mono-, tri-, and tetra-basie. a. Ortho-phosphoric acid PO(OH)3. or tri-hydrogen phosphate, is the common phosphoric acid H₃PO₄ as it is often written. Crystalline. Tri-basic. Obtained by boiling P2O5 with water, or by boiling meta-phosphoric acid PO,OH with OH,. "Boueearth," from which phosphorus is made, is Calcium ortho-phosphate (PO₃)₂Ca₃. Phosphates: all insoluble but those of alkaline metals. PO(OAg), is yellow, and soluble in NOOH, as well as in H2N. SH2 readily separates orthophosphoric acid from lead or silver ortho-phosphate. ${}^{2}PO_{4}Ag_{3} + {}^{3}SH_{2} = {}^{3}Ag_{2}S + {}^{2}PO_{4}H_{3}$. b. Pyrophosphoric acid or hydrogen pyrophosphate P203(OH)4 or P.O.H., Can be obtained in crystals. Silver pyro-phosphate is white. Prep. When orthophosphoric acid is heated to over 213° C., it loses OH, and becomes pyrophosphoric acid. ${}^{2}PO(OH)_{3} =$ OII₂ + P₂O₃(OII)₄. Also, when di-sodium hydroxyl orthophosphate is heated to low redness, it loses OH2 and on re-dissolving, gives sodium pyrophosphate. 2[PO(OH)'ONa)₂]-OH₂ = P₂O₃(ONa)₄. A pyro-phosphate, decomposed by sulphuric acid, yields orthophosphoric acid on boiling. Ordinary phosphoric acid is precipitated as MAGNESIUM-AMMONIUM ORTHOPHOSPHATE, ealcined and weighed as magnesium pyrophosphate P₂O₃O₄Mg₂, 100 parts of which contain 63.96 per cent. of P2O5. 3. Metaphosphoric acid, glacial, or hydrogen metaphosphate PO2OH or PO3H =80. Results from heating either ortho- or pyro-phosphorie acid to redness. $Prep. PO(OH_3)$ by heat = $OH_2 + PO_3H$. A substance resembling iee, very deliquescent and sour. Monobasie. Preeipitates albumen. Metaphosphates. Silver metaphosphate, white. When boiled with water, meta-phosphorie acid gives orthophosphoric acid. Phosphorus oxide P₄0 = 140. A red powder, always formed in the incomplete combustion of phosphorus. P and N. [Phospham HN2P contains H in addition. Yellowish-white, bulky powder. Obtained by heating PCl₃,5H₃N in a eurrent of carbonie anhydride.] P and S. [Six compounds are known. P₂S₃ and P₂S₅ are the analogues of the respective oxygen compounds. The compounds P2S, P2S3 and P2S5 form sulphur salts with metallic sulphides.] P and Se. [Three selenides known P₂Se, P₂Se₃ and P₂Se₅.] P and Cl. 1. Phosphorous chloride PCl₃ = 137.5. Colorless, fuming liquid, very volatile. Sp. gr. 1.45. Boils at 73°.8 C. Great solvent of phosphorus. Immediately decomposed by much water into hydrogen eliloride and phosphorous acid. $PCl_3 + 3OH_2 = 6ClH + POH(OH)_2$. Prep. by passing dry Chlorine into melted phosphorus in excess. 2. Phosphoric chloride PCl₅ = 238.5. White, erystalline solid, volatile below 100° C. Very deliqueseent. Easily prepared by saturating PCl₃ with Cl₂. By a large excess of water, it is instantly decomposed into hydrogen ehloride and orthophosphorie acid. Thus: $PCl_5 + 4OH_2 = 5ClH + PO(OH)_3$. Phosphoric oxy-chloride or phosphoryl chloride POCl₃ = 153.5. Limpid, volatile, fuming liquid, much used in ehemical research. Boils at 110° C. Prep. a. from phosphorie chloride with little water. $PCl_5 + OH_2 = 2ClH + POCl_3$. b. By heating phosphorie ehloride with phosphorie anhydride. $P_2O_5 + 3PCI_5 =$ e. By heating phosphorie ehloride with crystallized boracie acid. ${}_{3}PCl_{5} + {}_{2}(BOOH,OH_{2}) = 6ClH + B_{2}O_{3} + {}_{3}PCCl_{3}$. d. By passing O into boiling PCl3. [Phosphoric sulpho-trichloride PSCI3 = 169.5. Fuming, colorless liquid. Boils at 257° C. Prep by decomposing phosphorie ehloride PCl₅ with SH_2 . $PCl_5 + SH_2 = 2ClH + PSCl_3$. Or, by adding antimonous sulphide to phosphorie chloride. $Sb_2S_3 + 3PCl_5 = 2SbCl_3 +$ 3 PSCI3. When heated with sodium hydroxide, sulphoxyphosphate is formed; $PSCl_3 + 6NaOH = 3NaOl + 3OH_2 + PS(ONa)_3$.] P and Br. [Phosphorous bromide PBr3. Liquid, boils at 175°. 3 C. Phosphoric bromide PBr., Oxy-bromide POBr., P and I. [Diniodide of phosphorus, PI2 = 285. In prismatic crystals of orange color. Melts at 110° C. By dissolving Pin CS2, and adding iodine. Phosphorous iodide PI, Dark red, 6-sided plates. Fuses at 50° U.T

XV. Arsenicum As = 75. As, = 300.

A trial element, sometimes found in a free state, but chiefly in combination. MISPICKEL FeSAs; TIN-WHITE COBALT COAS,; COBALT-GLANCE COSAS; NICKEL-GLANCE NISAS; KUPFERNICKEL NiAs; ARSENICAL NICKEL NIAS, REALGAR As, S., ORPIMENT

As., S.

The vapor-density of arsenicum, compared with that of H, is 150, which is twice its atomic weight, so that its molecule (like that of P) occupies as vapor only half the volume of a molecule of H. 11.19 litres of arsenicum weigh 150 grammes. Steel-grey, metallie; erystallizes in rhombohedra. Very brittle. Tarnishes and loses all its lustre. Sp. gr. 5.7 to 5.9. Heated to 160° in close vessels, it volatilizes without fusion. vapor, slightly oxydized, has a garlie odor. Burns in air with bluish flame. Arsenieum-erust readily soluble in chloride of lime solution, and as powder, burns in Chlorine. NO.OH readily oxydizes it to arsenie acid AsO(OII). Prep. from arsenious anhydride by charcoal. 2As2O3 + 3C = 3CO2 + As4. Compounds. As with H. Arsine H₃As = 78. Or arsenietted hydrogen. Colorless gas of strong garlic odor. Fearfully poisonous. At -30° C., a colorless liquid. Heated to redness in absence of air, into steel-grey crust of As and H. Chlorine deposits a solid brown hydride. Presence of NO2OH most objectionable in presence of AsH₃, as solid hydride deposited. To be remembered in Marsh's test. Solution of SO₄Cu absorbs the gas, whilst Cu₃As₂ is deposited. Passed into NO₂OAg, silver is deposited, and arsenic acid found in solution. $H_3As + 8NO_2(OAg) + 4OH_2 = 8NO_2(OH) + 4Ag_2 + AsO(OH)_3$. Reinsch's test consists in deposit of Cu, As, upon a clean strip of copper in CIH solution containing arsenical compound. Burns in air with bluish flame, depositing white vapors of As,O3. Incompletely burnt, deposits arsenicum on cold surfaces, instantly dissolved by Cl. OCa. Prep. of H3As. From zine arsenide by dilute sulphuric acid. As with Cl. Arsenious chloride AsCl₃ = 181 5. Heavy, colorless, oily liquid, fuming. By water into ClH and As2O3. Arsenieum burus in Cl into AsCl3. Easily made by passing dry Chlorine over heated As2O3. [As with Br. Arsenious bromide AsBr. Deliquescent, colorless prisms. As with I. Arsenious iodide AsI₃. Brick-red solid of sp. gr. 4.39. As with F. Arsenious fluoride AsF₃. Funning colorless liquid, of sp. gr. 2.73. Boils at 63° C.] As and O. 1. Arsenious anhydride As₂0₃ = 198. Also arsenie trioxide, and white arsenic. Two modifications: vitreons and crystalline. The vitreous of sp. gr. 3.74, most soluble in water. The latter, at 100° only retains 11 per cent., and not more than 3 per cent. when cold. Very soluble in hot ClH. Poisonous: antidotes magnesia and precipitated ferric hydroxide Fe₂(OH)₆. Crystallizes in octahedra; rarely in prisms. Volatile without fusion at 193°.3 C. Its vapor contains one vol. of As and 3 vols. of O condensed into 2 vols. Arsenites. Arsenious acid As(OH)3, is tri-basic and feebly acid. Prep. of As₂O₃. By roasting arsenical ores: the As oxydizes and sublimes. Potassium ARSENITE As(OK)3, in Fowler's solution, used in medicine. ARGENTUM ARSENITE As(OAg)3, is canary-yellow, soluble in H₂N and in NO₂OH. CUPRIC HYDROXYL ARSENITE As(OH)(O₂Cu) or CuHAsO₃, is Scheele's Green, soluble in H₃N and in NO₃H. 2. Arsenic anhydride As, $0_s = 230$. Arsenic pentoxide. White powder, somewhat deliqueseent. Arsenic acid AsO(OH)3 or H₃AsO₄, is a tribasic acid like orthophosphoric acid. The only well-defined hydrate answers to Pyr-arsenic acid As₂O₃(OH)₄. By oxydation of As₂O₃ by means of NO₂OH, arsenic acid is obtained. Affords an easy method of preparing nitrous acid. $As_2O_3 + 3OH_2 + 2NO_2OH = 2AsO(OH)_3 + 2NOOH$. Arsenates. Many isomorphons with phosphates. Isomorphism: similarity in form with analogy of composition. Silver arsenate As0(0Ag)₃, liver-brown, soluble in H₃N and in NO, OH. CUPRIC ARSENATE AsO(OH)(O_2 Cu) is blue. As and S. a. Di-arsenicum disulphide As $_2$ S $_2$ = 214 "Realgar" Native, in ruby-red prisms. Insoluble in water, and in ClH. Prepared artificially 4As₂O₃ + $7S_0 = 4As_0S_0 + 6SO_0$. White Indian fire is a mixture of 2 parts realgar, 7 of sulphur and 24 of saltpetre. b. Arsenions sulphide $As_2S_3 = 246$. "Orpiment": aurum pigmentum. Oblique rhombic prisms of yellow color and brilliant lustre. Insoluble in water and in ClH. Very solnble in H₃N, in ammoninm carbonate, and sulphide. Also in KOH, Thus: $As_2S_3 + 4KOH = OH_2 + AsOH(OK)_2 + AsSH(SK)_2$. Salts: Sulpharsenites. c. Arsenic sulphide As, S, = 310. Yellow substance, by fusion of S2 with As2S3. Not precipitated from acid solutions of arsenie acid by $\tilde{S}I\tilde{I}_{2}$. $2AsO(OH)_{3}^{2} + 5SH_{2} = 5OH_{2} + As_{2}S_{3} + S_{2}$ Sulpharsenates. In sulpharsenites and sulpharsenates Sulphnr takes the place of Oxygen in the corresponding salts.] Sodium sulpharsenate AsS(SNa)₃.

End of the non-metallic elements.

Remarks.

The reader will have observed that all the oxides of nonmetallic compounds which are called anhydrides, are capable of forming acids. They one and all contain certain Radicles or unsaturated residues (see p. 2). Nitric acid, for example, may be looked upon as a molecule of water, in which nitric oxide NO has taken the place of an atom of Hydrogen. Now nitrogen is a triad element, and in the radicle NO₂, three out of the four bonds possessed by the dyad element oxygen are united with it: one bond is free or unsaturated, and therefore NO₂ is a compound monad radicle. Nitric acid contains OH, or water, minus one atom of hydrogen—the monad radicle which has received the name of hydroxyl. All the compound radicles among the non-metallic elements called acids, contain, according to their basicity, one, two, three or four atoms of hydroxyl. The acids are either monobasic (like NO.OH; NO₂OH; Cl.OH; ClO.OH; ClO₂OH, &c. &c.): dibasic like (SO₂(OH)₂); tribasic, like As(OH)₃ or tetrabasic like AsO(OH)₃.

There are also radicles, both simple and compound, which form salts of hydrogen. These are distinguished from acids or salts of hydroxl by the prefix hydrogen. Thus we have hydrogen chloride, hydrogen sulphide, hydrogen cyanide. Cl is a monad radicle, therefore ClH is a saturated compound, a salt of the mouad metal hydrogen. S is a dyad, and therefore SH₂ is hydrogen sulphide, the dyad united by its two combining powers with 2 atoms of the monad hydrogen. In hydrogen cyanide CNH, carbon having 4 combining powers, is united by 3 to nitrogen, and the monad radicle thus produced, is saturated.

rated by its union with H in CNH or prussic acid.

An acid, whether a compound of hydroxyl or of hydrogen, reflects the union of an electro-negative (radicle) with an electro-positive element or quasi-element. The Hydrogen or the Hydrogen of the hydroxyl may be exchanged for any other

Metal, and form so-called metallic salts.

The difference in the combining powers of the elements must now be comprehended. But it must also have been noticed that the same element may vary in its quantivalence. Thus nitrogen is a monad in N₂O; a triad in H₃N, and a pentad in N₂O₅. Even in the case of CYANOGEN there is reason to believe that the carbon is sometimes attached by its four combining powers to pentad N, leaving one of the bonds of the nitrogen free, instead of, as is generally the case, three of the carbon bonds uniting with the triad N, and C forming the connecting link of the radiele.

As the basicity of the acids is of great importance, the following Table will be found useful. It will also serve to familiarize the student with common methods of symbolism, and will prevent a slavish adherence to one moderate expression.

1. a. Monobasic acids.

Hydrogen chloride	ClH	Hydrogen fluoride .	FH
Hydrogen bromide	BrH	Hydrogen cyanide .	(CN)H
Hydrogeu iodide .	IH	Hydrogeu fluo-borate	BF ₃ ,FH

1. b. Monobasic acids as salts of (OH) or H.

B. The Metallic Elements.

As the elements are at least 64 in number, and only 15 have been considered among the non-metallics, the greater number is comprised in this group. Many of the metals are of small im-

portance, and indeed but little known.

All the metals oxydize. Some have so great an affinity for O that they can only be preserved under naphtha, or in perfect exclusion from the air. They may be represented as oxides of hydrogenium, in which the latter metal is displaced by an equivalent of another metal. In the oxides the whole of the H is displaced; in the hydroxides only a portion. E.g K₂O: KOH. The basic oxides may unite directly with the anhydrides to form metallic salts. Thus: $CO_2 + K_2O = CO(OK)_2$ POTASSIUM CARBONATE. With an acid or a salt of hydroxyl, the change to a metallic salt is simultaneous with the production of water. Thus: $K_2O + CO(OH)_2 = OH_2 + CO(OK)_2$. Again, if a hydroxide is brought to a salt of hydroxyl (a so-called acid), water is formed together with a metallic salt. E.g. $HOK + CO(OH)_2 = OH_2 + CO(OH)(OK)$ or $KHCO_3$. Frequently the basylous metal simply displaces H in OH. Thus: $K_2 + SO(OH)_2 = H_2 + SO(OK)_2$ or K_2SO_3 . In salts of hydrogen, the behaviour is very similar. Thus: $K_2O + 2ClH = OH_2 + 2ClK$. Again: $KOH + CIH = OH_2 + CIK$. And once more: $K_2 + 2CIH = H_2$ + 2ClK.

In the case of peroxides, they can only become basic by a loss of oxygen. This is well seen in the manufacture of Chlorine. There is no manganous salt corresponding with MnO₂; therefore, on addition of hydrogen chloride, one atom of Oxygen forms water with two atoms of H and sets Cl₂ free, the peroxide MnO₂ becoming Manganous oxide MnO, a base which immediately reacts upon further 2ClH to form OH₂, and MnCl₂.

Some few metals form anhydrides or acid oxides, but these

are more akin to the non-metals.

Most oxides are insoluble in water, and so also are most salts. The oxides of the alkaline metals and their salts are notable exceptions. The chlorides, nitrates and sulphates of the metals are nearly all soluble in water.

The metals themselves are good conductors of HEAT. Ac-

cording to Wicdemann and Franz they rank as follows:-

Silver 1000 Gold 981 Copper (rolled) 845 Copper (east) 811 Aluminum . 665	Iron (bar) Tin Steel	436 422 397	Lead Antimony	359 287 215
Zine, rolled . 641				

The metals are also good conductors of electricity. As a rule, good conductors of heat are also good conductors of electricity. The conducting power of metals is inversely proportioned to their resistance to the passage of the electric current. According to Matthicssen the electric conductivity of pure metals is as follows:—.

Copper	77.43 37.43 33.76	Potassium Lithium Iron .	. 20.8	4 Palladium. 5 Platinum. 6 Strontium. 4 Mercury.	6.71
Magnesium	27.71				

With reference to the SPECIFIC HEATS of metals in the solid state, experiment has proved that, if we take the atomic weights of the metals instead of equal weights for determining the specific heats, the numbers expressing the capacity for heat of the atoms are all equal. The METALS ALL POSSESS THE SAME ATOMIC HEAT. This will be at once understood by unltiplying the sp. heats of the metals (see Table below) by their respective atomic weights.

	Sp. heat.	A	tomic weigh	ut.	Atomic heat
Zinc	0.0950	×	65.2	=	6.390
	0.0310	\times	207.	==	6.410
Platiuum	0.0324	×	197.5	==	6.399

The slight differences arise from errors of experiment, and we may accept 6.4 as the common atomic heat of the metals. In the determination of the sp. heat, we have a means of ascertaining the atomic weight of a metal. For, if we divide the sp. heat

of the metal into 6.4, we obtain the atomic weight.

The elements in the solid state possess the same atomic heats as in their compounds. Hence is the molecular heat the sum of the atomic heats of the combined clements. [N, As, Cl, Br, I, Se and Te, have the same atomic heats as the metals. The atomie heats of P and S are found to be 5.40; of F 5.0; of O 4.0; of Si 4.7; of B 2.75; of H 2.3 and of C 1.76.]

The following Table of the specific Heats of the elements

contrasted with water and ice is from Regnault and others:

METALLIC LUSTRE, a feature of polished metals: wanting when in pulverulent state. OPACITY important: gold-leaf transmits green light. Color varies from the whiteness of silver to the yellow of gold, the pale yellow of barium; the red of copper, the bluish-white of lead, &c. Without odor. Insoluble in water. Hardness varies greatly; from softness of butter, to hardness of steel. [Mohs' scale of bardness in minerals. I. Tale (23 specimens of minerals). II. Gypsum or rocksalt (90). III. Calc-spar cleavable (71). IV. Fluorspar (53). V. Apatite crystallized (43). VI. Felspar oleavable (26). VII. Limpid quartz (26). VIII. Topaz (5). IX. Sapphire or corundum (1). X. Diamond (1).] BRITTLENESS affected by temperature. Bi, Sb and As may be pounded. TENACITY measured by force required to break. If Pb 1, then Cd 1.2 Sn 1.3 Au 5.6 Zn 8 Ag 8.9 Pt 13 Pd 15 Cu 17 Fe 26. MALLEABILITY the power of extension under rollers: Au first. Ag, Cu, Pt, Pd, Fe, Al, Sn, Zn, Pb, Cd, Ni, Co. Gold-leaf 250,000 of an inch thick. Ductility involves tenacity, or power of resisting tension. Au, Ag, Pt, Fe p 2 and Cu much alike; then Pd, Cd, Co, Ni, Al, Zn, Sn, Pb, Tl, Mg, L. As to Fusibility the metals rank thus:—

1. 11b to 1 obibilities the	
Mereury	Lead
Thallium	Cerium . Iridium . Osmium . Platinum . Rhodium . Tantalum . Titanium .

VOLATILITY very various. As, Hg, Te, Cd, Zn, K, Na and Ru can be sublimed.

As to Specific Gravity, the metals exhibit great variations.

Transancora						

The metals often occur crystallized; crystals are regular geometrical solids. [In certain positions crystals split regularly; CLEAVAGE. The flat surfaces developed by cleavage called faces or planes. The lines of junction of two planes, its edges; junction of two edges, a plane angle; the point where three or more edges meet, a solid angle. Planes similar, when corresponding angles equal, and edges proportional; edges similar when produced by the meeting of planes respectively similar at equal angles; angles similar when equal, and contained within edges respectively similar. In crystals extra faces often formed by the replacement of an edge or the truncation of an angle. When faces quite equal and similar, called simple forms; those resulting from a combination of two or more simple ones, secondary or compound forms. Great variations in the angles of crystals; instruments of measurement called Goniometers. SIX CLASSES OF CRYSTALS. I. The regular, tessular, or cubical system: three equal axes around which the crystal symmetrically arranged, crossing each other at right angles. In cubes; salt, fluor, iron-pyrites, alum, garnet, diamond, gold, silver, copper, lead, iron, mercury, &c.; in octahedra; alum, magnetite, chrome-iron ore, white arsenic, diamond and many metals: in tetrahedra; copper pyrites, grey copper ore or fahlerz, blende: in rhombic dodecahedra; cobalt-glance, garnet, diamond, fluor, and many metals. Crystals possessing the completest symmetry, called homohedral forms: those derived from the former, hemihedral.—II. The right square prismatic, or pyramidal system. Three axes at right angles to each other, two only equal,—the third axis longer or shorter. Includes the long square prism; tinstone, zircon, apophyllite, idocrase: the short square prism; zircon, &c.: the octahedral square prism: apophyllite, zircon, &c.; and the long square octahedron; anatasc, tinstone, zircon, &c. —III. The rhombic system. Four axes; three of equal lengths in the same plane, crossing each other at angles of 60°, the fourth, perpendicular to these, may vary in length. forms are: the obtuse rhombohedron; Iceland spar, tourmaline: the acute rhombohedron; Iceland spar; the hexagonal prism; emcrald, quartz, tourmaline: the bi-pyramidal dodecahedron: quartz, apatite; and the scaleno dodecahedron; calcite or dogtooth spar.—IV. The right rectangular prismatic system. Three axes, all unequal and all at right angles to each other. Includes the right rectangular prism; heavy spar, prolinite, nitre:—the right rhombic prism: topaz, sulphur, prehnite, heavy spar; the octahedral rhombic prism; topaz, sulphur:—and the rhombic octaliedron; harmatome, sulphur, topaz, &c .- V. The oblique system. The three axes may all be of unequal length; two cross obliquely, the third is perpendicular to the others. Includos: the oblique rectangular prism; felspar, epidote, mica:

the oblique rhombic prism; selenite, augite, sphene:—and the oblique rhombic octahedron; felspar, selenite, &c.—VI. The doubly oblique or anorthic system. All the axes of unequal length and all cross obliquely. Includes: the doubly oblique prism; axinite, blue vitriol, &c.:—and the doubly oblique octahedron; albite, axinite.]

When a body crystallizes in two irreconcilable forms, it is said to be dimorphous; when in three, trimorphous. Pulverulent bodies, without any regular form, are called amorphous. Crystallized bodies, with similarity in form and analogy of composition, are called isomorphous. E.g. KCl. KI. KF. K(CN).

The metals combine together to form alloys: they are not so well-defined as those of the metals with O, S, Se, Cl, Br, I, F, &c. The melting-point is often below that of the constituent metals. Alloys of mercury called amalgams.

Metals of the alkalies.

		Sy	mbol.		At. weigh	ht.	Sp. gr.
Potassium			K	=	39.I		0.865
Sodium			Na	=	23.		0.972
Lithium			\mathbf{L}	=	7		0.593
Caesium			Cs	=	133		
Rubidium			Rb	=	85.4		1.520
(Ammoniu	m)		H_4N	=	81		

I. Group. Metals of the alkalies. They displace one atom of H from the H of the hydroxyl, or the H of the acids: hence monovalent. Their basic oxides and hydroxides are very soluble in water, and strongly alkaline to test-paper. Their carbonates are also soluble and alkaline.

I. Potassium or Kalium K = 39.1. $K_2 = 78.2$.

Discovered by Davy in 1807. Never native. Brilliantly-white metal, volatile at a red-heat, with green vapor. Sp. gr. 0.865. Melts 62° . 5 C. Oxydizes so rapidly that it must be kept under naphtha, or hermetically sealed. Decomposes OH_2 , the H burning with rose-colored flame in air, and dissolves as hydroxide KOH. Absorbs CO, and yields potassium rhodizonate $C_5O_4H_2(OK)_2,OH_2$. Prep. 1. By electrolysis of moist KOH: K_2 at the zincode. 2. By strongly heating $CO(OK)_2$ with $C_2 = 3CO + K_2$. 3. By heating KOH to whiteness with ironfilings. $4KOH + 3Fe = Fe_3O_4 + 2H_2 + 2K_2$. Only one basic oxide. Three oxides. K_2O , K_2O_2 , K_2O_4 . 1. Potassoxide $K_2O = 94.2$. White, deliqueseent caustie. Finses at red-heat. By

oxydizing K_2 in dry air. Contained as silicate in felspar, mica, &c. With water: **Hydroxide** HOK = 56.1. Hard, greyishwhite, deliquescent solid. Sp. gr. 2.2. Fuses without change of composition, but volatile at a white-heat. Very soluble in water, and heats greatly; from which in acute rhomboids HOK, 20H2. Rose color to flame. Next to caesium and rubidium hydroxides, potassium hydroxide the most powerful base. Precipitates nearly all metallic hydroxides from their solutions. Thus: Cl₂Ba + 2HOK = 2ClK + Ba(OH)₂. NO₂OAg $+ \text{ HOK} = \text{NO}_2\text{OK} + \text{HOAg}$. $\text{Cl}_6\text{Fe}_2 + 6\text{HOK} = 6\text{ClK} + 6\text{HOK}$ Fe₂(OH)₆. Liquor potassæ of Pharmacy contains about 6 per cent. of HOK. Prep. From dissolved CO(OK)₂ in about 10 parts of water, adding calcium hydroxide (OH), Ca boiling, decanting, evaporating and fusing in silver or wought iron. $CO(OK)_2 + (OH)_0Ca = CO(O_0Ca) + 2H0K$. HOK is soluble in alcohol; carbonate not, and they are thus separated. [Potassium TETROXIDE K.O.4. Chrome-yellow powder, formed in heating K, in dry air or oxygen. In water gives off O2, and furnishes solution of the PEROXIDE K2O2.] Sulphides: 5 sulphides. SK2. S_2K_2 . S_3K_2 . S_4K_2 . S_5K_2 . Potassium sulphide SK_2 . Doubtful. Mixed with charcoal, pyrophoric. $SO_2(OK)_2 + 4C = 4CO$ + SK2. POTASSIUM SULPH-HYDRATE HSK, by passing SH2 into $HOK = OH_2 + HSK$. 2HSK into $S_2K_2 + OH_2$ by O of air: then vellow. Potassium trisulphide S₃K₂, by passing vapor of CS_0 over heated $CO(OK)_2$. Thus: $3CS_2 + 2[CO(OK)_2] = 4CO$ + CO₂ + 2S₃K₂. Also contained in liver of sulphur. Potas-SIUM TETRASULPHIDE S4K2, by reduction of SO2(OK)2 in CS2 vapor. Pentasulphide S, K, is sulphate, in which S, substitutes O4. By fusing any sulphide with S. Hepar sulphuris is a mixture of higher sulphides with sulphate and thiosulphate of potassium. Again: $6 \text{HOK} + 6 \text{S}_2 = 30 \text{H}_2 + 2 \text{S}_5 \text{K}_2 + \text{S}_2 \text{O}(0 \text{K})_2$. SULPHATE SO2(OK)2 in hard 6-sided prisms, terminated in 6sided pyramids. Soluble in 16 of OH2. Decrepitates when heated. HYDROXYL SULPHATE SO, OHOK in flattened rhomboidal prisms, soluble in 2 of water. The residuum in the manufacture of NO.OH from NO₂OK by SO₂(OH)₂ = NO₂OH + SO₂OHOK.—Potassium carbonate CO(OK)2; the pearlash of commerce, obtained by incinerating plants, as a white, granular, delique scent salt; when recrystallized is CO(OK)2, 2OH2. HYDROXYL CARBONATE CO(OH)(OK) in right rhombic prisms, soluble in 4 of water. By solution in hot water into sesqui-carbonate 2[CO(OK)2],CO(OH)2: by heat into carbonate. - ORTHO-SILICATE Si(OK), META-SILICATE SiO(OK). See Glass.—NITRATE NO, OK, nitre or saltpetre. In 6-sided striated prisms, with dihedral summits. Soluble in 34 of cold and 4 of boiling water. Cooling, saline tastc. Insoluble in alcohol. Fuses at 339° C.: sal prunelle. By continued heat into fotassium nitrite NOOK; finally into O_4K_2 and OK_2 ,

with evolution of O, N. NO, &e.; HOK now prepared from pure nitre by heating to redness one part of NO,OK, with two parts of copper foil, and solution in water. Gunpowder a mixture of 74.8 parts of nitre, 11.9 of sulphur, and 13.3 parts of charcoal. In detonation: $4NO_2OK + S_2 + 6C = 6CO_2 + 2N_2 + 2SK_2$. In the residue, ehiefly $SO_2(OK)_2 + CO(OK)_2$; in fact, like all changes, not so simple as they look. Chlorate Clo.OK, rhomboidal scales of pearly lustre, soluble in 16 of cold and 2 of boiling Melts at 400° C, and at higher temperature: into PERCHLORATE, ehloride and O2, and the perehlorate into chloride and O_0 . Thus: $2ClO_2OK = ClK + ClO_3OK + O_0$. Then $ClO_3OK = ClK + 2O_2$. By SO_4H_2 : $2SO_4H_2 + 3ClO_2OK = OH_2 + 2SO_4HK + ClO_3OK + 2ClO_2$. Prep. By passing Cl_2 in excess into a thin paste of calcium hydroxide and potassium chloride, and separating the salts by crystallization. 2CIK $+\text{Cl}_2\text{O}_4(\text{O}_2\text{Ca}) = \text{Cl}_2\text{Ca} + 2\text{ClO}_2\text{OK}$. Also: $3\text{Cl}_2 + 6\text{HOK} = 5\text{ClK} + \text{ClO}_2\text{OK} + 3\text{OH}_2$. Perchlorate ClO₃OK, in needles, requiring 6 parts of water. CHLORIDE CIK in cubes, volatile at high temperatures. Soluble in 3 parts of water. Twenty-five per cent, of kelp. Bromide BrK, also in eubes. Used in medicine and in making Bromine. 2BrK + MnO, +3SO, (OH), $= 2SO_2OHOK + SO_2O_2Mn + 2OH_2 + Br_2$. IODIDE IK cubes, very soluble in water, less in alcohol. Does not brown with ClH (absence of iodate). FLUORIDE FK, in deliquescent cubes. CYANIDE CNK in deliquescent cubes. Insoluble salts. Potas-SIUM PLATINIC CHLORIDE 2ClK, Cl, Pt, a yellow salt, insoluble in mixed alcohol and ether. 100 parts contain 15.98 parts of K, or 19.26 parts calculated as OK2. SILICO-FLUORIDE 2FK,F,Si. Used in making SiF4.

The spectrum of potassium flames is distinguished by the presence of two bright lines; one in the red and another in the

violet.

II. Sodium or Natrium Na = 23. $Na_2 = 46$.

A beautiful reddish-tinted metal, erystalline. Sp. gr. 0.972. Fuses at 97°.6 C. Volatile. Burns with yellow flame. Decomposes water. $Na_2 + 2OH_2 = H_2 + 2H0Na$. Must be kept in hermetically-sealed tubes, or under naphtha. Prep. of Na. $CO(Na)_2 + 2C = 3CO + Na_2$. Two oxides: only one basic. ONa_2 and O_2Na_2 ; the latter, or PEROXIDE by burning Na_2 in O_2 . Sodium oxide $ONa_2 = 62$. Resembles OK_2 . By water into hydroxide HONa. White, fusible, deliquescent solid. Prep. from carbonate: $CO(ONa)_2 + (OH)_2Ca = COO_2Ca + 2HONa$. [Sodium sulphides. SNa_2 . S_2Na_2 . S_3Na_2 . S_4Na_2 . S_4Na_2 . S_5Na_2 .] Sodium salts soluble in water. Sodium chloride ClNa. "Common salt," the commonest salt of sodium. Cubes, soluble in $2\frac{1}{2}$ parts of water at $15^{\circ}.5$ C. Fuses at red-heat, and volatilizes.

Antiseptic. Source of ClH. ClNa + SO₂(OH)₂ = SO₂OH(ONa)₄ + ClH p. 18. Then, by greater heat: ClNa + SO₂OH(ONa) = SO₂(ONa)₂ + ClH. Bromide BrNa, in sea-water. Iodide in sea-water and in kelp. In cubes. Source of iodine (p. 21). 2[Na + MnO₂ + 3SO₂(OH)₂ = 2[(SO₂OH(ONa))] + SO₂O₂Mn+ 2OH₂ + I₂. Sulphate SO₄Na₂, toOH₂. In 4-sided prisms soluble in 2 of water. Effloresces and loses all its water. Aperient: "Glauber's salt." Hydroxyl sulphate SO₂OH(ONa). Very acid; non-deliquescent. By hcat: a. ${}_2SO_2OH(ONa) = OH_2 + SO_2(ONa)_2,SO_3$; then, b. $SO_2(ONa)_2,SO_3 = SO_4Na_2 + SO_4ONa_2$ SO₃. Sulphite SO(ONa)₂, 10OH₂. Oblique, efflorescent prisms, soluble in 4 of water. Thiosulphate SSO(ONa)₂,5OH₂ is the sodium hyposulphite of commerce. Used in photography. SODIUM CARBONATE CO(ONa), or 100H, or Na2CO3, 10OH2, in oblique rhombic prisms, soluble in 2 of water. Effloresees, fusible. Prep. a. Of "salt cake": $2\text{ClNa} + \text{SO}_2(\text{OH})_2 = 2\text{ClH} + \text{SO}_2(\text{ONa})_2$. b. of "black-ash," or "ball-soda." $\text{SO}_2(\text{ONa})_2$ $+ 4C = 4CO + SNa_2$. $5SNa_2 + 7[CO(O_2Ca)] = 5SCa, 2CaO +$ 2CO₂ + 5CO(ONa)₂, and this carbonate loses much of its CO₂ and becomes ONa2 at the high temperature. The black-ash therefore contains from 20-27 per cent. of sodium oxide: the black-ash dissolved in water, evaporated and crystallized as CO(ONa)2,10OH2, and the mother-liquor containing HONa, evaporated, mixed with saw-dust, roasted in a reverberatory furnace, and residue is the soda-ash of commerce. Re-dissolved and crystallized as CO(ONa)2,100H2. SESQUI-CARBONATE 2C0(0Na)₂,C0(0H)₂,20H₂ is "Trona salt," or "Natron," found native in rhombic prisms terminated by 4-sided pyramids. SODIUM HYDROXYL CARBONATE CO(OH)(ONa), is "bi-carbonate of soda." A white powder, soluble in ten parts of water. Its solution, made in the cold, does not precipitate solution of magnesium sulphate, which distinguishes it from the carbonate of sodium. ORTHO-SILICATE Si(ONa),. Glass is a mixture of various silicates, chiefly sodium and calcium silicates. Sodaglass is more brilliant than potash-glass, but has a greenish tint. See Calcium for glass (p. 46). Sodium di Borate ONa, 2B,0,100H, is "Borax." Native in Thibet; in flattened 6-sided prisms with tri-hedral summits. Soluble in 12 of cold, and half their weight of boiling-water. "Tincal" in commerce. By heat intumesces, loses its water and melts into a clear bead. A good flux, and solvent of metallic oxides. Source of BORACIC ACID BO(OH), OH .. SODIUM NITRATE NO (ONa), native in Atacama, Iquique, &c. In obtuse rhomboids, soluble in 2 of water. Somewhat deliquescent. 85 parts NO2ONa yield as much NO2OH as 101 1 parts of NO2OK. Phosphates. a, orthophosphates. ORTHOPHOSFHATE OF SODIUM PO(OH)(ONa), 120H2, is the rhombic phosphate, or DI-SODIUM HYDROXYL PHOSPHATE. Oblique-rhombic prisms of saline taste, soluble in 4 of water. [Solution alkaline, added to neutral silver nitrate, yellow precipitate of silver ortho-phosphate and free nitric acid: PO(OH)(ONa), + $_3NO_2(OAg) = _2NO_2(ONa) + NO_2OH + PO(OAg)_3$. By adding HONa, we obtain OH, and TRI-SODIUM PHOSPHATE PO(ONa)3, 120H, in 6-sided prisms. But, by adding ORTHO-PHOSPHORIC acid PO(OH), to di-sodium hydrogen phosphate, we obtain two molecules of: sodium DI-HYDROXYL ORTHO-PHOSPHATE PO(OH), ONa. Sodium-ammonium-hydroxyl-orthophosphate $PO(\tilde{O}Na)(\tilde{O}NH_4)(OH)$, $4OH_2$ is "microcosmic salt." Transparent, efflorescent prisms. Prep. $ClH_4N + POOH(ONa)_2 = ClNa$ + PO(ONa)(OH)(OH,N),4OH₂. b. pyrophosphates. Sodium PYROPHOSPHATE P₂O₃(ONa), 10OH₀. In prisms. By heating POOH(ONa), to low redness, and erystallizing from water. Thus. ${}_{2}POOH(ONa)_{2} = OH_{2} + P_{2}O_{3}(ONa)_{4}$. c. metaphosphates. Sodium metaphospiiate PO2ONa. Transparent glass. By igniting $PO(OH)_{o}ONa = OH_{o} + PO_{o}(ONa)$. Or, by igniting microcosmie salt. POONaOH, NOH = OH, + H, N + PO, ONa. SODIUM PLATINIC CHLORIDE 2ClNa, Cl4Pt, in striated yellow prisms, very soluble in water. Insoluble salt. DI-HYDRIC PYR-ANTIMONATE OF SODIUM Sb.O. (OH)2(ONa)2,6OH2.

The spectrum of Sodium is distinguished by one fine bright double line of yellow color, identical in position with the dark

solar line called D.

[III. Lithium L = 7. $L_2 = 14$.

A white, lustrous metal, fusible at 180° C. Sp. gr. 0.59. The lightest solid known. From λίθος, a stone. Very oxydizable. Volatile at a rcd-heat. Prep. from fused ClL by electrolysis. One basic oxide. Lithium oxide OL₂. Discovered by Ariwedson in 1818. Lithium hydrate HOL, far less soluble than HOK and HONa. Fuses below rcd-heat, and destroys platinum vessels. Lithium salts in various mineral waters and in the ashes of plants. Chloride ClL, 2OH₂, most deliquescent. Purple color to flame. Very soluble in mixed alcohol-ether, in which ClK and ClNa insoluble. Carbonate CO(OL)₂, sparingly soluble in water. Lithium sulphate SO₂(OL)₂, OH₂, in flat tables, very soluble. Addition of solution of barium-hydroxide, removes the radiele, and gives lithium hydroxide. Lithium ortho-phosphate PO(OL)₃, insoluble in alkaline phosphates and in alkaline solutions, but very soluble in dilute acids.

Sources of lithium, besides springs, are: LEPIDOLITE F(LK), $O_3Al_2, 2SiO_2$. Spodumene of triphane $3O(LNa)_2, 4O_3Al_2, 15SiO_2$. Petalite $3O(LNa)_2, 4O_3Al_2, 3oSiO_2$. Pounded, and ignited with twice their weight of Calcium oxide. The mass is first treated with ClH, then with $SO_2(OH)_2$, and the $SO_2(OL)_2$ separated by

water from the little solublo $SO_2(O_2Ca)$. Solution of barium hydroxide will change $SO_2(OL)_2$ into $z(HOL) + SO_2(O_2Ba)$.

By the spectroscope, traces of Lithium discoverable by a brilliant crimson band, which has a refrangibility between that of the lines B and C of the solar spectrum.

[IV. Caesium Cs = 133. $Cs_2 = 266$.

Discovered by Bunsen and Kirchoff in 1860 in a spring at Dürkheim. More electro-positive than potassium. The name from cresius, lavender-blue, in allusion to the two brilliant bands produced by it in the spectrum of a gas-flame. Traces of the chloride in the ash of tobaceo, bect-root, coffee and grapes. A rare mineral "Pollux," from Elba, contains 32 per cent. Forms a crystalline amalgam with mercury. Very oxydizable. Two oxides: one basic. Caesium oxide OCs₂. Caesium hydroxide HOCs, very deliquescent and caustic. The most powerful base. Salts. ClCs in cubes. SO₂(OCs)₂, very soluble. NO₂OCs, isomorphous with NO₂OK. CO(OCs)₂, deliquescent. COOHOCs, in brilliant prisms. Caesium platinic chloride 2ClCs, Cl₄Pt; the least soluble of the platinic salts.]

[V. Rubidium Rb = 85.4. $Rb_2 = 170.8$.

Discovered by Bunsen and Kirchoff. More electro-positive than potassium. Brilliant silver-white metal of sp. gr. t.52. Melts at 38°.5 C. The name from rubidus, dark-red, because the spectrum of its salts exhibits a remarkable pair of red lines, less refrangible than Fraunhofer's line A. Most oxydizable. Like caesium it is contained in certain springs; in the ashes of some plants, and in a variety of Lepidolite. Two oxides: one basic. Rubidum oxide ORb₂. Hydrate HoRb is deliqueseent. CIRb, in cubes; very deliqueseent. SO₂(ORb)₂ in hard, brilliant prisms. Forms alums like sulphates of K₂, Na₂, Cs₂ and (NH₄)₂. Carbonate CO(ORb)₂, deliqueseent. Rubidum plating chloride 2CIRb,Cl₄Pt, only less soluble than the respective Caesium compound.]

Ammonium $(H_1N) = 18.(?)$

The salts of the hypothetical metal Ammonium are best considered in this place, as they closely resemble those of potassium. Many indeed are isomorphous (similar in form, and analogous in composition). So-called ammonium-amalgam is formed by addition of a solution of ClH₄N to amalgam of sodium. Breaks up spontaneously into H and H₃N.

Ammonium must not be mistaken for nitrogen hydride, or

ammonia H₃N. p. 8. H₃N unites with many metallie salts. Thus with: ClAg, 2H₃N. Cl₂Ca, 6H₃N. Cl₂Ca&H₃N. SO₂(O₂Cu), 4H₃N, OH₂. NO₂(OAg), 3H₃N. When H₃N and dry CO, are brought together, we obtain AMMONIUM CARBAMATE CONH, (OH, N). CAR-BAMIC ACID CONH, (OH), has not been isolated. One atom of amidogen H₂N displaces 1 atom of OH. So-ealled CARBAMIDE CO(NH₂), would be formed by substituting NH₂ for OH, and this happens when ammonia and carbon-oxychloride COCl, are brought together. Ammonium sulphamate SO, NH, OH, N, results, when SO₃ and 2H₃N are brought together. With acids, it is different: we have salts of ammouium. Ammonium hydrogen SULPHIDE SH(H, N) is the common test for the metals, precipitating in neutral solutions, black sulphides of ferrous, cobalt and nickel, white zinc sulphide and aluminum hydroxide, flesheolored manganous sulphide, and greenish chromium hydroxide. Prep. by saturating H₃N with SH₂. Absorbs O and becomes yellow disulphide $\bar{S}_2(H_4N)_2$. Thus: $8SH(H_4N) + 5O_2 = 4OH_2$ $+2[S_2(H_4N)_2]+2[S_2O(OH_4N)_2]$. Dissolves as sulphur salts the electronegative sulphides; with evolution of SH₂. An-MONIUM CHLORIDE $ClH_4N = 53.5 = 4$ vols. Or H_3NClH . Semitransparent, tough, fibrous. In cubes, octahedra or fern-shaped. Soluble in less than 3 parts of water. IODIDE I(HAN). NITRATE NO₂O(H₄N), source of N₂O at 250° C, and of 2OH₂. Striated prisms. NITRITE NO(OH4N); by heat into 2OH2 and N2. SULPHATE SO, (OH, N), in prisius, soluble in two of cold water. CO(OH₄N)₂. Sesquicarbonate of ammonium CARBONATE 2[CO(OH₄N)₂],CO₂. "Smelling-salts." By loss of AMMONIUM CAR-BAMATE COH₂N(OH₄N), into AMMONIUM HYDROGEN CARBONATE CO(OH)(OH, N) (two molecules). Prep. by subliming ammonium chloride with calcium carbonate: 6ClH₄N+3CO(O,Ca) = 3Cl₂Ca + OH₂ + 2H₃N + sesquicarbouate. Ammonium sodium hydroxyl phosphate PO(OH)(OH, X)(ONa), 4OH, is microcosmic salt. Insoluble salt. Ammonium Platinic Chloride 2ClH₄N,Cl₄Pt, yellow powder; eontains 7.62 per eeut. of H₃N.

Metals of the alkaline earths.

	Symbol.		At. weight	t.	Sp. gr.
Barium .	. Ba	=	137		4.000
Stroutium	\cdot Sr	=	87.5		2 540
Calcium .	. Ca	=	40		1.578

Dyad metals which decompose water at ordinary temperatures. Their oxides are strongly basic, alkaline, soluble as hydroxides. Carbonates insoluble in water; bi-carbonates are soluble. Most of their salts are insoluble in water. In solution, they can be separated from the alkalies by boiling with animonium carbonate.

VI. Barium Ba = 137.

Dyad metal of silver-white color. It is mallcable, melts below red-heat, and oxydizes readily. Name from βαρύς, heavy. From fused Cl₂Ba by electrolysis. Two oxides. BaO and BaO₂. One basic: BARIUM OXIDE BaO. Grey and fusible. BARIUM HYDROXIDE (OH ,Ba, erystallizes with 8OH,; soluble in 20 of cold and 2 of boiling water. Solution strongly alkaline: test for CO. Also used for making certain hydroxides from their sulphates. Thus: $SO_2(OK)_2 + (OH)_2Ba = SO_2O_2Ba + {}_2HOK$. Very poisonous: antidotes, Sodium or Magnesium sulphate. Prep. a. by heating (NO2)2O2Ba to redness. b. by boiling solution of barium sulphide with Cuprie oxide. 6SBa + 5OH, +8CuO = 4SCu₂ + \hat{S}_2 O(O₂Ba) + 5(\hat{O} H)₂Ba. BARIUM DIOXIDE or PEROXIDE BaO2. Grey. HYDRATE BaO2,60H2. Used for making O_2H_2 , p. 7. Also a source of Oxygen. *Prep.* BaO heated in a stream of dry air = BaO₂. Also by fusing ClO_2OK with BaO. ClO₂OK + 3BaO = ClK + 3BaO₂. Dissolve in water and BaO2,6OH2 separates. Sulphide of Barium BaS. strongly heating SO Ba with charcoal = 4CO + BaS. Hydrated SULPHIDE BaS, 60H2, in colorless erystals. When dissolved in water: 2BaS + 2OH₂ = (OH)₂Ba + BaS,SH₂. Barium sulphide used for making soluble Barium salts. Soluble salts. BARIUM CHLORIDE Cl. Ba, 20H, in flat 4-sided tables, soluble in 2½ parts of water. Yellowish-green color to flame. Test for soluble earbonates, phosphates, sulphates, &c., as these salts are insoluble in water, but soluble in ClH except SO4Ba. Insoluble in aleohol. Barium nitrate $(NO_2)_2(O_2Ba)$. Oetahedral. Soluble in 8 parts of cold and 3 of boiling water. Less soluble in CiH and in NOOH. Green-fire is a mixture of 45 parts of dry nitrate, with 15 of S, 10 of ClO2OK, 21 of lamp-black and 11 of S₂Sb₂. Requires great eare in mixing. Barium Chlorate (ClO2)202Ba. Beautiful green color to flame. ACETATE, 3OH2, in flattened prisms. Barium thiosulphate S20(02Ba),0H2, in small, brilliant crystals. Insoluble salts. BARIUM SULPHATE SO.Ba. Native as "heavy spar" in right rhombic prisms and massive. Sp. gr. 4.59. Source of Barium salts by ignition with charcoal: into sulphide. Used for adulterating white lead. Insoluble in ClH or NO2OH. CARBONATE OF BARIUM CO(O.Ba). Native as "Witherite" in 6-sided prisms, terminated by 6-sided pyramids. White powder, soluble as Cl₂Ba or (NO₂)₂O₂Ba in the respective acids: CO2 evolved. BARIUM SILICOFLUORIDE F.Ba,F.Si. Chromate CrO.Ba, yellowish powder. Barium is weighed as SO, Ba, containing 65.66 per cent. of BaO.

The spectrum of barium contains a number of characteristic

green lines, by which it is easily detected.

VII. Strontium Sr = 87.5.

A dyad metal of yellow color. Sp. gr. 2.54. Harder than lead. Decomposes cold water. The name from Strontian in Argyleshire, where Hope discovered "Strontianite," the carbonate of strontium. Prep. from fused CHLORIDE, Cl.Sr. Two oxides, Sr0 and Sro., Only one basie; Strontium oxide Sro. White. From (NO,),(O,Sr) at a red-heat. With water, hydroxide Sr(OH). Its Hydrate Sr(OH), 8aq. requires 50 parts of eold and 24 of boiling water for solution. Strongly alkaline: a test for CO₂. ISTRONTIUM PEROXIDE Sro. By O, over heated Strontium oxide.] Sulphide SSr. From SO₄Sr + 4C = 4CO + SSr. Salts of strontium: soluble in water. CHLORIDE Cl. Sr, 60H,. Deliquescent needles, very soluble in alcohol and thus separable from Cl₂Ba. Burns with crimson flame. NITRATE (NO.), O.Sr. 50H₂, octahedra soluble in 5 of water. ("Red-fire" a mixture of 80 parts of dry nitrate, 22 parts of S, 20 parts of ClO,OK and 5 parts of lamp-black. Great eare required in mixing: no pounding in mortar.) CHROMATE CrO₄Sr. Silico-fluoride F.Sr.F.Si. Insoluble salts. Sulphate of Strontium SO.Sr. native as "Celestine" in right-rhombie prisms of bluish huc. Often accompanies S in Sicily. Carbonate COO.Sr, native as Strontianite. Phosphate Pooho, Sr., white powder. Strontium estimated as SO₄Sr, containing 56.52 per cent. of SrO. The spectrum is most characteristic.

VIII. Calcium Ca = 40.

A dyad metal, never native. Light-yellow color. Sp. 1.578. As hard as gold, mallcable and duetile. Tarnishes slowly in dry air. Decomposes OH₂ immediately. Burns magnificently when heated in O into CaO; in Cl, into Cl, Ca. Prepared from fused mixture of 2Cl₂Ca with Cl₂Sr, by electrolysis. Also from I, Ca by Na, = 2NaI + Ca. Two oxides: CaO and CaO₂. One basic oxide: Calcium oxide Ca0 = 56. The well-known "Quieklime." White, eaustie, infusible. In oxy-hydrogen an intense light: lime-light. With water it combines, heats and slakes: into CALCIUM HYDROXIDE (OH) Ca or "slaked lime," soluble in 700 parts of cold and 1280 parts of boiling water. Alkaline. Absorbs CO₂: a test. Absorbs SH₂ as OH₂ and SCa. Excess of (OH) Ca in lime-water, called "milk of lime." Calcium hydroxide in mortars, cements, &c. Prep. by heating CALCIUM CARBONATE CO(O₂Ca) to redness: CO(O₂Ca)=CO₂ + CaO. [Cal-CIUM PEROXIDE CaO2,80H, is precipitated by adding line-water to sodium peroxide Na2O2.] Calcium sulphide SCa. White, insoluble in water. Phosphorescent. Prep. SO, Ca + 4C =

4CO + SCa. Chief constituent of soda-waste. When moist. absorbs O, and supplies calcium thiosulphate, S2O(O2Ca). Thus: ${}_{2}SCa + OH_{2} + {}_{2}O_{2} = Ca(OH)_{2} + S_{2}O(O_{2}Ca)$. [CALCIUM PENTA-SULPINDE S, Ca. By boiling S, with (OH), Ca, we obtain thiosulphate as well. Thus: $3[(OH)_2Ca] + 6S_2 = 3OH_2 +$ S₂O(O₂Ca) + 2S₃Ca. CALCIUM PHOSPHIDE P₂Ca₂? By distilling P_2 with CaO. $7P_2 + 14$ CaO = $2[P_2O_3O_4Ca_2] + 5P_2Ca_2$.—Calcium SILICIDE SiCa₂ in lead-grey scales. By ClH into SILICONE or CHRYSEON Si₆0, H₆.] Salts of calcium: soluble in water. Chlo-RIDE Cl.Ca, 60H., in striated, deliquescent prisms. Saturated solution boils at 179°.5 C. By heat at 150° C. into Cl₂Ca, 2OH₂; porous, used for desiccating gases. Found in sea-water. Artificially: COO₂Ca + 2ClH = OH₂ + CO₂ + Cl₂Ca. Absorbs H₃N. [Bromde Br₂Ca. Iodde I.Ca.] Oxy-chloride Cl₂OCa, see p. 19. "Chloride of lime." Evolves Cl₂ in air. Made from ealeium hydroxide by absorption of Cl2. According to Kolb, $\text{Cl}_4\text{O}_6\text{H}_6^*\text{Ca}_3$ by solution in water into: ${}^2\text{OH}_2 + \text{Cl}_2\text{Ca}$ $+ (OH)_2Ca + (OCI)_2Ca. - CALCIUM CHLORATE (CIO_2)_2O_2Ca,$ deliquescent. NITRATE (NO2)2O2Ca in deliquescent prisms. CALCIUM BI-CARBONATE CO(O, Ca).CO(OH)2, in Calcareous waters. Deposited as COO2Ca in so-ealled "stalactites" and "stalagmites." "Temporarily hard" waters contain it: softened by boiling or addition of Calcium hydroxide; - Clark's process. Sulphate So202Ca, 20H2. Transparent, flattened prisms as "Selenite." Rectangular prisms as "Anhydrite" SO₂(O₂Ca). Mussive, found as alabaster. Soluble in 400. Heated below 260° C., loses its water and forms "gypsum" or "Plaster of Paris." Contained in all spring-waters. CALCIUM TETRA-HYDROXYL ORTHO-PHOSPHATE P202(OH)4(O2Ca) is so-ealled "superphosphate" when yet mixed with SO2(O2Ca) in manure. Used in making P2. Insoluble calcium salts. Calcium carbonate CO(O₂Ca) = CaCO₃ = 100. As marble, limestone, oolite, chalk, &e. In coral, shells, &e. Dimorphous, rhombohedral in "Iceland spar" and in 6-sided right rhombic prisms in "Aragonite." $Cl_2Ca + CO(t)Na)_2 = 2ClNa + COO_2Ca$. Calcium fluoride F_2Ca . In cubes, octahedra and massive in "fluorspar." Used for ornaments, and for making FH and 2FH, SiF4 (pp. 23, 25) Calcium orthophosphate P2O2(O2Ca)3 in bone-earth. Native as Apatite F₂Ca,3[P₂O₂(O₂Ca)₃.] Is precipitated by phosphates from soluble calcium salts with 2OH₂. [Sodium-calcium BORATE [2(, BO,ONa,O2Cal)]B2O3, 18OH2], native at Iquique. Pern.

Calcium is precipitated quantitatively as oxalate C₂O₂O₂Ca, and weighed as carbonate CO(O₂Ca), which contains 56 per cent.

of CaO.

The spectrum of Ca is peculiar, containing a number of distinct bright lines.

The Magnesian Group.

	Symbols.	At. weight.	Sp. Gr.	Melting-point.
Magnesium	. Mg	= 24 .	. 1.743	
Zinc				
Cadmium .	. Cd	= 112 .	. 8.604	. 228° C.
Glucinum.	. Be	= 9.3.	. 2.100	. 900° C. (?)

The metals belong to the dyad group and are volatile and combustible. Only one oxide. Their carbonates are soluble in ammonium earbonate.

IX. Magnesium Mg = 24.

A dyad metal, never native. Silver-white, malleable and duetile. Sp. gr. 1.743. Very slowly oxydizes in damp air, to magnesia. Nearly as volatile as zinc. Burns brilliantly when heated in O, in Cl, Br, I, Svapor, &c. Its combustion in air, a substitute for sunlight in photography. Unites directly with N. Dissolves in HCl evolving H₂. Precipitates Zn, Fe, Co and Ni from solutions of their salts. With As and Sb salts, acidulated, Mg gives rise to H₃As and H₃Sb. Prep. of Mg. From Cl₂Mg + Na₂ = 2ClNa + Mg. Also from fused chloride by electrolysis. One oxide: basic. Magnesium oxide Mg0 = 40. White, infusible, alkaliue. As HYDROXIDE (OH), Mg requiring 5142 parts of water at o° C. for solution, and over 36,000 parts at 100° C. Is precipitated as such, from all its soluble salts by any of the preceding hydroxides. Thus: (OH), Ca + Cl, Mg = Cl, Ca + (OH) Mg. Prep. by heating magnesia alba: then called magnesia usta. Sulphide SMg sparingly soluble. By S₂C in vapor over red-hot MgO + C. Nitride NoMg, is erystalline. Salts of magnesium : soluble in water. Chloride Cl. Mg, white, deliquescent. Used in making Mg. In prisms as Cl. Mg, 60H. OXY-CHLORIDE MgCl2, MgO, sets with water like plaster of Paris. Browne BroMg, in sea-water. Magnesium Sulphate SO₂(O₂Mg), 70H₂, "Epsom salt." Right rhombic prisms soluble in 3 of cold and 14 of boiling water. Nauseous taste. In sea and other waters. Springs at Epsom. Prep. from mother-liquor of sea by calcium hydroxide and the hydroxide of maguesium by SO₆(OH), into sulphate. Or, from dolomite by SO₂(OH)₂, and separation of resulting sulphates by water. NITRATE (NO2)202Mg,6011, deliquescent prisms. Insoluble salts. Magnesium carbonate COO₂Mg = 84. Native as "magnesite," white, hard, amorphous. The most abundant magnesian mineral is "Dolomite," a carbonate of calcium and magnesium CO(0,Ca), CO(0,Mg), valuable as building-stone (Houses of Parliament). From a solution in Co, as CO(0, Mg), 30H2. Magnesia alba of Pharmacy is a basic carbonate, a varying mixture of the carbonate with (OH). Mg. Magnesium

hydroxyl ortho-phosphate PO(OH)(O2Mg), 7OH2, in minute needles. Ammonium magnesium orthophosphate PO(OH.N) (0.Mg)60H., known as "triple phosphate." Quite insoluble in H.N. By heat into: Magnesium pyrophosphate P.O. (O. Mg)., (H₃N and OH₂) containing 36.21 per cent. of MgO. Magnesium estimated as such. [Silicates are very important minerals. MnO and FeO often substitute, in part, or entirely, MgO and CaO. Chrysolite Si(O₂Mg)₂. Meerschaum 2[SiOO₂Mg], SiO₂, 4OH₂. Tale 4[SiOO, Mg], SiO2, 4OH2. Steatite or soapstone 3[SiOO2Mg], SiO., Serpentine 2[SiOO2Mg](OH)2Mg,OH2. Augite is magnesium and calcium silicate, in which Fe and Mn interchange. Hornblende is also a silicate of Mg, Ca, Al and Fe, with FK and F.Ca. Asbestos is a variety of hornblende.

X. Zinc Zn = 65.2.

A dyad metal, never native. Bluish-white, hard and lustrous. Sp. gr. 7.146. Melts at 412°C.; boils at 1040°C. It is brittle, but between 100°C. and 150°C., it is malleable and duetile. Oxydizes very slowly, hence used for eoating sheet-iron. Readily attacked by Cl, Br and I. Dissolved by the acids. $Zn + SO_2(OH)_2$, $2OH_2 = SO_2O_2Zn + 2OH_2 + H_2$. $Zn + 2ClH = Cl_2Zn$ $+ H_2$. $3Zn + 8NO_0OH = 3[(NO_2)_2O_2Zn] + 4OH_2 + 2NO_0Also_0$ by POTASSIUM HYDROXIDE: Žii + 2HOK = H2+OK2, OZn. Zine, the electropositive element in most batteries; the wire attached to it is the zincode or negative pole. Precipitates most metals. but is precipitated by all the preceding. Burns with luminous greenish light into its one oxide, ZnO. One basic oxide: Zinc oxide ZnO = 81.2. White amorphous powder, insoluble in water. Canary-yellow whilst red-hot. "Tutty" is impure ZnO. Isomorphous with MgO. Zinc hydroxide (OH)2Zn, is white, gelatinous, insoluble in water, soluble in H₃N and in HOK. ZING SULPHIDE SZn. Native as Blende, the common ore of zinc: in rhombie dodecahedra. Its HYDROSULPHIDE OH, SZn is white and insoluble in HOK. Not precipitated in acid solutions of zinesalts by SH2, but in neutral by SHII4N. Metallurgy: when roasted, SZn, into Zn0 + SO2: then ZnO is reduced by chargoal $2Z_{\rm HO} + C = CO_2 + 2Z_{\rm H}$. Salts soluble in water. Chloride $Cl_2Z_{\rm H}$. White, deliquescent, fusible at 100° C. An escharotic. Also forms "Burnett's disinfeeting liquid." Sulphate \$0,0,Zn, 70H2, in colorless 4-sided prisms; effloreseent. "White vitriol." Soluble in 22 parts of cold water. Used in medicine and by calieo-printers. Insoluble salts. Zinc carbonate COO₂Zn, native as Calamine the best ore of zine. White, when pure. Metallurgy. By roasting = $Zn0 + C0_2$. Then the oxide reduced by charcoal, and distilled. Precipitated as a basic carbonate 3C00, Zn, 5[(OH)2Zn],OH2. Silicate Si(O4Zn2),OH2 is also a mineral

ealled electric calamine. Zine is best weighed as ZnO; 100 parts contain 80,24 of Zine.

XI. Cadmium Cd = 112.

A dyad metal, never native. Tin-white, malleable and ductile. Melts at 228°C; boils at 860°C. Sp. gr. 8.6. volatile than zinc, the ores of which it accompanies. Tarnishes but little in air. Burns when strongly heated in air, depositing brownish fumes of the oxide. Readily dissolved by CIH, by SO₂(OH)₂, 2OH₂ and by NO₂OH. Only one oxide: basic. CAD-MIUM OXIDE CdO = 128. Brown. Hydroxide (OH)₂Cd is white, insoluble in HOK, soluble in H₃N. Cadmium sulphide SCd, yellow. Native as "Greenockite," in 6-sided prisms. Its HYDRATE (OH)2SCd, yellow, is precipitated by SH, from solutions of cadmium salts, and may thus be separated from zinc-salts. The metal Cd, obtained by roasting SCd, and reducing the CdO with charcoal. In Zinc-ores containing Cadmium, the latter, being more volatile, may be received apart as long as brown filmes are deposited. Soluble salts. Chloride Cl2Cd, 2OH2, 4-sided prisms. IDDIDE I2Cd, in pearly scales. NITRATE (NO2), O.Cd. SULPHATE SO₂O₂Cd, 4OH₂ very soluble. Insoluble salts. Carbonate of cadmium, COO, Cd, white, and insoluble in ammonium carbonate: thus separated from zine as carbonate. Estimated as oxide CdO, which contains 87.5 per cent. of metal.

[XII. Glucinum or Beryllium Be = 9.3.

A dyad metal, never native. White, lustrous, malleable and ductile. Sp. gr. 2.1. Fusible at 900° C.? Does not decompose CIH and SO₂(OH)₂, 2OH₂, dissolve it as ehloride and sulphate: H₂ evolved. NO₂OH only a feeble action. Prep. from Cl₂Be + Na₂ = 2ClNa + Be. Only one oxide: basic. Beryllium oxide Be0 = 25.3. White, insoluble in water. Hydroxide(OH)2Be, gelatinons, white, and soluble in ammonium carbonate, and so, easily separated from aluminum hydroxide. Absorbs CO. from the air, and displaces H3N from its salts. Glueinum aluminate Al, O,, BeO occurs native in the gem "chryso-beryl." Soluble salts. Sweet: hence γλυκύς sweet. Glucinum chloride Cl. Be, sublimes in white needles. Crystallizes Cl. Be, 40H2. SULPHATE SO₂O₂Be, 40H₂, in octahedra. No alum. SO₂(0K)₂, SO, O, Be, 2aq. Insoluble salts. Ortho-silicate Si(O, Be,), native as Phenakite. The "emerald" or "beryl" (sometimes so elear as to have been used in Brillen, spectacles) is double silicate of aluminum and beryllium 3 BeO, Al.O., 6SiO. After removal of the SiO₂, as F₄Si, by treatment with F₂Ca and SO₄H₂, the resulting sulphates can be easily, in part, separated by ammonium

sulphate which forms an "alum" with the aluminum. Au reste, bervl-hydroxide is soluble in ammonium earbonate. Estimated as beryllium oxide Be0.]

Metals of the earths.

	Symbol.	At. weight.		
Aluminum	. Al	= 27.50		
Yttrium .	. Y	= 92.00		
Erbium .	. E	= 168.90		
Lanthanum	. La	= 139.00		
Didymium	. D	= 144.75		
Cerium .	. Ce	= 138.00		

These are triads, or pseudo-triads. Their oxides are of an earthy character, and have the most powerful affinity for oxygen. They are precipitated as hydroxides by ammonium sulphide.

XIII. Aluminum Al = 27.5.

Tetrad in aluminum ethide (C2H5)4Al; as pseudo-triad in chloride (Cl3Al). Never native. Discovered by Woehler in 1827. White metal with bluish tint, malleable, duetile. Sp. gr. 2.6. Fuses at about 450° C. Burns with bluish-white light in oxygen. Inalterable in air: used for weights. Not attacked by NO_2OH ; easily by ClH. $6ClH + Al_2 = {}_3H_2 + Cl_6Al_2$. Dissolved by potassium hydroxide. Alloys. Aluminum bronze Cu, Al. Prep. of Al. a. by electrolysis of fused 2ClNa, ClaAl. b. 2ClNa, Cl₆Al₂ + $_3$ Na₂ = $_3$ ClNa + $_2$ Al. c. from Cryolite with sodium; 6FNa,F₆Al₂ + $_3$ Na₂ = $_1$ 2FNa + $_3$ Al₂. Only one oxide: basic. Aluminum oxide O₃Al₂ = Al₂O₃ = 103. Native as "corundum" in 6-sided prisms; emery is pounded corundum. "Sapphire" and "ruby" are tinted Al₂O₃. Pure aluminum oxide is white, and fusible in oxy-hydrogen. After strong ignition, insoluble in acids. United with various bases to aluminates. Chryso-beryl Al₂O₃,BeO. Spinelle ruby is Al₂O₃,MgO. Gahnite Al₂O₃,ZnO. Sodium aluminate (ONa₂)₃Al₂O₃ is made from Bauxite, a hydrated aluminum ferrie-oxide. Aluminum hydroxide (OH)₆Al₂, yellowish, translueent mass. "Diaspore" is a natural hydroxide (OH)₂O₂Al₂ or OH₂,Al₂O₃. Soluble in HOK; insoluble in H₃N. The basis of "elay." Sulphide S₃Al₂: by burning Al in the vapor of sulphur. Salts soluble in water. ALUMINUM CHLORIDE Cl₆Al₂ = 268. Crystalline, translucent; sublimes at a dull red-heat. Deliquescent. ClaAl2,120H2 in 6-sided prisms. $Al_2O_3 + 3C + 3Cl_2^1 = 3CO + Cl_6Al_2$. Aluminum sulphate $(SO_2)_3(O_2)_3Al_2$, 180 H_2 in thin scales, soluble in two parts of water. Prepared by decomposing elay with $SO_2(OH)_2$. Potassium alum $(SO_4)_4K_2Al_2 240K_2$, in octahedra and in cubes, soluble in 18 of cold and 2 of boiling water. Loses 10 of OH_2 at 100° C., and other 10 OH_2 at 120°, and the rest at 200° C.: alumen ustum. Ammonium alum containing $(NH_4)_2$ in place of K_2 , is prepared from the H_3N of gas-works, mixed with acid alumiuum sulphate. All true monad metals may substitute K_2 . Thus Na_2 , Cs_2 , Rb_2 , L_2 , Tl_2 , Ag_2 . Isomorphous salts, e.g. $[(SO_4)_4Na_2Al_2, 24OH_2.]$ $[(SO_4)_4(NH_4)_2, Al_2, 24OH_2.]$

[(SO₄)₄L₂Al₂,24OH₂.] Insoluble salts. Aluminum fluoride F.Al. As "Cryolite," in Greenland. 3FNa, F₆Al₂. Contains 13 per cent. of aluminum. Ortho-phosphate PO(O₃Al). The "turquoise" is a hydrated phosphate P_2O_5 , $2Al_2O_3$, $5OH_2$. Clay is a hydrated aluminum silicate $2SiO_2$, Al_2O_3 , $2OH_2$. Felspars. "Orthoclase" or "adularia" is potassium felspar. Si0,4AlK,2Si0, or 6Si0,Al,0,K,0. "Albite" is sodium felspar, and "Labradorite" calcium felspar. "Pumice" is altered felspar. "Obsidian" is fused pumice. "Granite" is a mixture of quartz, felspar and mica—the latter consisting of magnesium and aluminum silicate. "Syenite" contains Hornbleude instead of mica. "Garnets" are basic double silicates of calcium and aluminum. Glass is a mixture of various insoluble silicates with excess of silica. Bohemian glass is $SiO_{\bullet}(OK)_2$, $SiO_{\bullet}(O_2Ca)_4SiO_2$. [$K_2O_{\bullet}3SiO_2$, $CaO_{\bullet}3SiO_2$.] Crown-glass $SiO_{\bullet}(OK)_2$, $SiO_{\bullet}(O_2Ca)_2SiO_2$. Flintglass. $SiO_{\bullet}(OK)_2$, SiO(O2Pb)4SiO2. In this glass, lead replaces calcium. Bottleglass contains aluminum and iron silicates, besides calcium and potassium silicates. It contains more basyl than the other varietics. [See Miller's 'Iuorganic Chemistry,' revised by MeLeod, p. 420.]

[XIV. Yttrium Y = 92.

Is a triad metal, never native. Burns brilliantly in O₂. The name, from Ytterby in Sweden, where "Gadolinite," a silicate of yttrium, glucinum, cerium and iron, is met with. *Prep.* from the chloride, by sodium. One basio oxide: Yttria Y₂O₃, uearly white powder, of sp. gr. 4.842. Salts colorless. Sulphate (SO₄)₃Y₂, 8OH₂. Colorless solution which does not exhibit an absorption spectrum.]

[XV. Erbium E = 168.9.

The metal probably a triad. Not isolated. One basic oxide. Erbium oxide E_2O_3 . Faint rose-red color. Infusible, but glows with intense green light, exhibiting in spectroscope a continuous spectrum intersected by a number of bright bands. Sulphate $(SO_4)_3E_2$, SOH_2 , in rose-colored crystals.]

[XVI. Lanthanum La = 139.

Discovered by Mosander in 1841 "hidden," λανθάνω I lie hid, in Cerium. A triad metal never native. Only one basic oxide. La₂O₃, buff-colored. Hydroxide (OH)₃La. Chloride LaCl₃. Sulphate (SO₄)₃La₂. Salts colorless, precipitated by soluble oxalates. No absorption spectrum.]

[XVII. Didymium D = 144.75.

A triad metal, so named because of its close association (from δίδυμος twin) with Lanthanum. Discovered by Mosander. One basic oxide: Didymium oxide D₂O₃. White. Peroxide DO₂, brown. Salts rose-colored. Sulphate (SO₄)₃D₂,80H₂, isomorphous with erbium and yttrium sulphates. Salts exhibit a well-marked absorption-spectrum, containing two black lines inclosing a very bright space.

[XVIII. Cerium Ce = 138.

A triad metal never native. Discovered by Klaproth in 1803. The metal little known. Forms two basic oxides. Cerous oxide Ce₂O₃ and Ceric oxide CeO₂. CEROUS OXIDE Ce₂O₃, greyish-blue powder, easily changed into CeO₂ by air. Salts colorless. Oxalate used in medicine. CERIC OXIDE CeO₂ is formed when Ce, O, or (OH), Ce are ignited in an open crucible. Yellowishwhite; orange-red whilst red-hot. Hydroxide 3(OH₂), 2CeO₂ is of bright-yellow color. Salts yellow, and brown-red. No ceric chloride, as CeO, behaves like MnO, towards ClH, yielding CeCl₂.7

Metals more or less allied to iron.

	Symbol.		At. weight.		Sp. gr.	
Ferrum .		Fe	=	56		7.84
Manganesiur	n	Mn	=	55		10.8
Chromium		Cr	=	52.2		7.81
Cobalt		Co	=	58.8		8.95
Nickel		Ni	=	58.8		8.28
Uranium .		U	=	120		18.40

This group includes the magnetic metals, as well as the diamagnetic Uranium. They decompose water at a red-heat. SH2 in acid solntions, does not precipitate salts of these basyls.

XIX. Ferrum Fe = 56.

Very rarely native, except in meteorites, and in mica-slate at Canaan in Connecticut. Almost silver-white: of sp. gr. 7.844. The most tenacious of metals, also the most magnetic. Unchanged in dry air, and in pure water free from O and CO. Rusts in damp air. Burns when heated in O into magnetic oxide. Dilute sulphuric acid and hydrogen chloride dissolve it freely. Thus: SO_4H_2 , $2OH_2 + Fe = SO_4Fe + 2OH_2 + H_2$. 2ClH+ Fc = CloFe + Ho. Strong nitric acid renders it passive; dilute, dissolves Fc as (NO2)2O2Fc. Fe decomposes steam at a red-heat: Fe₃ + 40H₂ = 4H₂ + Fe₃O₄. "Meteorites" contain in addition to iron, nickel and cobalt, together with traces of copper, manganesium, chromium, tiu, magnesium, carbon, sulphur and phosphorus. Bar-iron contains from 0.2 to 0.4 per cent. of carbon. When strongly heated it softens, and can be "welded" by hammering. Prep. by strongly heating filings of bar-iron mixed with 1 of pure Ferric oxide: thus are all traces of C and Si oxydized at the expense of the oxide, and a fusible slag formed. Melts at 1530° C. Iron is dyad, as well as pseudo-triad, or hexad, in its chief combinations. Ores of iron. Ferroso-ferric oxide or "magnetite" Fe₃O₄, both massive and in octahedra. Gives, by reduction with charcoal, the purest iron. "Specular iron-ore" $\mathbf{Fe}_2\mathbf{0}_3$, in rhomboids from Elba and Formosa. "Red hæmatite" $3(\mathbf{0H}_2), 2\mathbf{Fe}_2\mathbf{0}_3$, both fibrous and compact: soluble in ClH as Cl₆Fe₂. When roasted, it loses its water and is easily reduced by coal or charcoal. "Spathic iron-ore" CO(0, Fe), in yellowish, lenticular crystals, as well as massive. By roasting it oxydizes, and loses CO2; resulting Fc2O3 is reduced by fuel. "Clay iron-stone" is an impure ferrous earbonate, mixed with clay, limestone, &c.: it is the chief iron-ore of Great Britain, and is reduced in the blast-furnace, roasted: thus Fe₂O₃ obtained. Lime CaO is admixed, in order to prevent the SiO, of the ore from uniting with FeO; the SiO, forms a fusible CALCIUM ORTHOSILICATE SiO4Ca2 or "slag," and coal is added to reduce the ferric oxide. The "cast-iron" or "pig-iron" contains both carbide and silicide. Three kinds of cast-iron; grey, mottled and white. In white cast-iron, all the carbon is combined. "Spiegeleisen" contains about 5.08 per cent. of carbon, answering to CFc4. It is the most fusible. The mottled cast-iron is coarse-grained and contains visible points of uncombined carbon or graphite. The grey cast-iron contains more uncombined carbon than the mottled: it is soft and more fusible than the mottled: when heated, and suddenly cooled, used for making chilled shot. Cast-iron, into wrought. "Refining:" carbon burnt out and Si got rid of as FERROUS SILICATE Si(O2Fe)2. "Puddling" removes yet more C and Si. By Siemens' process, malleable iron direct from the ore, previously mixed with lime and 25 per cent. of small coal, heated in a horizontal rotatory furnace by means of a regenerative gas furnace. Alloys. "Red short iron" is tough at ordinary temperatures, but brittle at red-heat. Contains S, As and Cu. "Cold short iron" is brittle at common temperatures: made from finery cinder Si (O.Fe), and always contains Phosphide of iron. Steel contains from 0.7 to 1.7 per cent, of carbon. In the cementation process, iron unites with 1.5 per cent. of carbon. In "Bessemer" steel, wrought-iron is worked up with a sufficient quantity of "spiegel-eisen" to give at once the necessary amount of carbon. By means of a blast of air under pressure of 12 to 25 lbs. per square inch, the melted pig-iron has its carbon burnt into CO, and when thus de-carbonized, it is mixed with the right proportion of spiegel-ciscn. Oxides. Two basic oxides, besides an intermediate one. 1. Ferrous oxide FeO. 2. Ferric oxide Fe₂O₃. 1. Ferrous Oxide FeO = 72. Very unstable per se. Its HYDROXIDE (OH), Fe is white, unstable, passing by oxydation through light-green, bluish-green, black and red-brown, to ferric hydrate. 2. Ferric oxide Fe₂O₃ = 160. Red-brown. Red hæmatite and specular iron-ore are varieties. "Rouge" is ferric oxide. Its hydroxide 3(OH)22Fc2O3 is red-brown and bulky. Precipitated, and dried at 100° C., (OH2), Fe2O3. 3. FERROUS-FERRIC OXIDE Fe0, Fe, O3 is black; hydroxide also. Forms no specific salts. S and Fe. Ferrous sulphide SFc = 88. Reddish-brown. Either by direct union of the elements or by heating FeS2 with Fe. FcS is used in making SH2. Thus: 2ClH + SFe = SH₂ + Cl₂Fe. Ferrous salts are precipitated as black hydrated sulphide by S(H₄N)H. Thus: Cl₂Fe + OH₂ $+S(H_1N)H = SFe,OH_2 + ClH + ClH_4N$. Ferric disulphide $FeS_2 = 120$. "Iron-pyrites" or "Mundic," in cubes of brassy lustre or massive. Sp. gr. 4.98. Also as "marcasite" in right rhomboidal prisms. When roasted in air, gives SO, and Fc, O3: chief source of SO2 in making sulphuric acid (p. 15). Heated in absence of air, yields Sulphur: ${}_3S_2Fe = \acute{S}_4Fe_3 + S_2$. "Arsenical pyrites" or mispickel SAsFe. MAGNETIC SULPHIDE S₈Fe₇, is soluble in HCl (S₂Fe not).—Phosphide PFe₂ hard and brittle: in "cold short iron." 1. Soluble ferrous salts. FERROUS CHLORIDE Cl2Fe white and volatile. In crystals Cl2Fe,40H2, green and very soluble. Ferrous 10DIDE I2Fe,40H2 in green crystals. I2 + Fe = I2Fe. NITRATE (NO2)202Fe,60H2 in palegreen rhomboids; very unstable. Ferrous sulphate SO, Fe, 70H2. In rhomboids of sca-green color, soluble in 2 of water. "Green vitriol." Its solution absorbs O and deposits BASIC FERRIC SULPHATE SO_3 , 2Fe_2O_3 , 3OH_2 . Thus: ${}^2OSO_4Fc + {}^5O_2 + {}^6OH_2$ = $6(3SO_4Fc_2) + 2$ of basic salt. Becomes red-brown on exposure: hence copperas or "Couperose." It loses water, and by further heat: ${}_{2}SO_{4}Fe = Fc_{2}O_{3} + SO_{2} + SO_{3}$. See p. 14, Nordhausen Sulphuric acid. A good reducing agent. See Gold. Ferrous bi-Carbonate CO(O2Fe), CO2, in chalybeate waters: absorbs O and deposits Ferric hydrate. 2. Insoluble ferrous salts: Ferrous carbonate $\rm CO(O_2Fe)=116$. White. "Spathic ironore." Precipitated as greenish hydrated carbonate by soluble carbonates. Ferrous hydrogen ortho-phosphate $\rm PO(OH)(O_2Fe)$, white: becomes blue. Ferrous ortho-silicate $\rm Si(O_2Fe)_2$, is "finery slag." Ferric salts. Soluble. Ferric chloride $\rm Cl_6Fe_2=325$, in brown scales. $\rm Cl_6Fe_2+6OH_2$ in red, deliquescent crystals. Reduced by $\rm SH_2$. $\rm Cl_6Fe_2+ClH+SH_2=2(Cl_2Fe)+3ClH+S$. Ferric Iodide $\rm I_6Fe_2$. Ferric sulphate $\rm (SO_4)_3Fe_2$, yellowish-white, deliquescent. "Coquimbite" with $\rm 9OH_2$, silky-white mineral. Alums, in which $\rm Fe_2O_3$ takes the place of $\rm Al_2O_3$ in the common alums. Isomorphous. Thus: $\rm (SO_4)_4K_2Fe_2$, $\rm 24OH_2$. Ferric nitrate $\rm (NO_3)_6Fe_2$, $\rm 12OH_2$. Insoluble ferric salts. Basic ferric sulphate already mentioned. Ferric phosphate $\rm POO_3Fe, 2OH_2$, is white, and insoluble in acetic acid. "Vivianite" $\rm PO(OH)(O_2Fe), \rm 2PO(O_4Fe), \rm 8OH_2$.

Ferric acid $FeO_2(OH)_2$ is scarcely separable, so immediately does it evolve O, and deposit ferric hydrate. Potassium ferrate $FeO_2(OK)_2$ is very soluble in water, to amethystine solution. Thus: $(OH)_6Fe_2 + 3Cl_2 + 10KOH = 6ClK + 2FeO_4K_2 + 8OH_2$. Iron is estimated as Ferric OXIDE Fe_2O_3 , containing 70 per cent. of the metal. A ferrous, easily changed into a ferric salt by NO_2OH . Thus: $6SO_4Fe + 2NO_2OH + 3SO_4H_2 = 2NO + 4OH_3$

+ 3(SO₄)₃Fe₂.

XX. Manganesium Mn = 55.

Discovered by Gahn in 1774. Never native. Dyad and tetrad; also a pseudo-triad in manganie oxide Mn₂O₃. Greyishwhite, brittle metal. Sp. gr. 8.or. Oxydizes speedily in air; decomposes water slowly, and must be preserved under naphtha. Its alloy with iron, harder and more elastic than iron. Prep. by heating manganous carbonate to whiteness, with charcoal, in a smith's forge. Oxides. Two basic, two indifferent and two acids. 1. Manganous oxide MnO = 71. A powerful base. Olive-green. Absorbs O when ignited and changes into brown Mn₃O₄. By heating COO₂Mn in a stream of H to keep off the air = CO₂ + Mn0. Hydroxide (OH₂)MnO is white, soluble in H₃N, especially in presence of salts of H₄N. Salts. Pink or rosered. MnO is isomorphous with MgO, ZnO, FeO. 2. Manganio oxide Mn₂O₃ = 158. In acute, square-based octahedra as "Braunite." Also as "manganite" OH₂,Mu₂O₃, in brilliant, right-rhombic prisms. Very feeble base. Isomorphous with Fe₂O₃ and Al₂O₃. Substitutes these bases in "alums." Gives a violet color to glass, and a red color to the amethyst. 3. Manganous-manganic oxide Mn₃O₄ = MnO₃Mn₂O₃, native in "Hausmannite." Obtained by igniting MnO, CO(O₂Mn) or Mn₂O₄. Not basic. 4. Manganese dioxide or peroxide MnO₆

= 87. The chief ore; "pyrolusite," in steel-grey, rhombic prisms. "Varvicite" Mn₂O₃,2MnO₂,OH₂. "Wad" is a hydrate. Much used in the arts. Not basic. Ignited, gives 0. 3MnO. = $Mn_3O_4 + O_2$. Also when heated with sulphuric acid: 2MnO_2 $+ 2SO_4H_2 = 2SO_2(O_2Mn) + 2OH_2 + O_2$. With hydrogen ehloride gives Cl. $4\text{ClH} + \text{MnO}_2 = 2\text{OH}_2 + \text{MnCl}_2 + \text{Cl}_2$. Decomposed in presence of SO_1H_2 by oxalic acid $C_2O_2(OH)_2 = 2CO_2 + 2OH_2$ + SO₂O₂Mn. Gives its own weight of CO₂ nearly. 5. Manganic acid MnO2(OH)2. Green, unstable. Isomorphous with SO,(OH)2, FeO2(OH)2, and CrO2(OH)2. Manganates. MnO4K2 is "mineral chamælion." Condy's disinfectant is principally Mno, Na2. Deeomposed by water into permanganate, sodium hydroxide and manganese dioxide. A little free acid, thus: 4SO₄H₂+ $5 \text{MnO}_4 \text{K}_2 = 40 \text{H}_2 + 3 \text{SO}_4 \text{K}_2 + 2 \text{Mn}_2 \text{O}_8 \text{K}_2 + \text{SO}_4 \text{Mn}$. By sulphurous acid: $2 \text{SO}(0 \text{H})_2 + \text{MnO}_4 \text{K}_2 = \text{SO}_4 \text{K}_2 + \text{SO}_4 \text{Mn} + 20 \text{H}_2$. 6. Permanganic anhydride, Mn₂O₇. Deep-green unstable liquid. Permanganic acid Mn₂O₆(OH)₂, a brown crystalline mass best known in its salts. Violet and amethystine. Potassium PERMANGANATE $Mn_2O_6(OK)_2 = 316.2$. In needles. $3 \text{MnO}_2(\text{OK})_2 + 2 \text{CO}_2 = \text{MnO}_2 + 2 \text{CO}(\text{OK})_2 + \text{Mn}_2 \mathbf{0}_6(\mathbf{0K})_2.$ Or: ${}_{2}{\rm MnO}_{4}{\rm K}_{2}+{\rm Cl}_{2}={}_{2}{\rm KCl}+{\rm Mn}_{2}{\rm O}_{6}({\rm 0K})_{2}.$ Sulphides. Manganous sulphide SMn, native as "manganese blende." As hydrated sulphide SMn, OH2, when a manganous salt is precipitated by ammonium sulphide; flesh-color but oxydizing and browning on exposure. Manganous salts. Soluble in water. CHLORIDE Cl₂Mn, 40H₂, in tablets of pink hue, very deliquescent. May be purified from Cl₈Fe₂ in the residues of Cl₂ manufacture, by boiling with CO(O2Mn) or with SMn,OH2; Mn takes the place of Fe in solution. MANGANOUS SULPHATE SO4Mn,70H2 in prisms at 5° C. Otherwise with 50H₂. Insoluble salts. Manganous carbonate CO(0₂Mn), native as "manganese spar" of pink hue, isomorphous with CO(O₂Ca), CO(O₂Fe), &c. Precipitated as: 2[CO(O₂Mn)],OH₂. Phosphate PO(OH)O₂Mn, white powder. Borate B₂O₂(O₂Mn), white. Manganic salts. Manganic CHLORIDE ClaMn2; dark-brown. By heat into 2Cl2Mn + Cl2. MANGANIC SULPHATE (SO4)3Mn2, with SO4K2, forms MANGANIC ALUM (SO,), MnK2,240H2.

XXI. Cobaltum Co = 58.8.

Never native. Dyad in its chief oxide. Trivalent in its cobaltic salts which are very unstable. Discovered by Brandt in 1733. Reddish-white, brittle metal fusible in wind-furnace. Sp. gr. 8.95. Very tenacious. Magnetic. Slowly dissolved by ClH and dilute SO₄H₂,2OH₂. Readily by NO₂OH. *Prep.* from exalate by white heat. Arsenide As₂Co, is "tin-white cobalt" or "speiss-cobalt," the best ore. Arsenio-sulphide

SCoAs, is "Cobalt glanee," in cubes, dodecahedra, and oetahedra. Oxides: two basic, and one intermediate. 1. Cobaltous oxide CoO = 74.8. Greenish-grey. Strong base. By roasting, it absorbs O and becomes Co₃O₄. Used as a pigment. Hydroxide CoO,OH, is rose-eolored, readily soluble in ammonium earbonate. Salts blue or pink. "Zaffre" is an impure oxide. "Smalt" is a glass colored blue by cobaltous silicate. The ore is roasted, so as to oxydize the cobalt, but to leave the associated Niekel, Iron and Copper combined with arsenicum and sulphur, as arsenides and sulphides: it is then slowly fused with potassium earbonate and silica. A glass of potassium and cobalt silicate results, ealled "Smalt." The so-called "speiss" at the bottom of the erucible consists mainly of sulphides and arsenides of Ni. Fe and Cu. 2, Cobaltic oxide Co.O. is black. Its hydroxide (OH), Co, also black. Prep. by passing Cl2 through cobaltous hydroxide suspended in solution of potassium hydroxide. $3[CoO(OH_2)] + Cl_2 = Cl_2Co + (OH)_6Co_2$. By gentle heat into Co₃O₄. Very feeble base. Cobaltous sulphide SCo is black. Hydrate OH, CoS also black, and precipitated thus from solutions of cobaltous salts by SH(H₄N). Cobaltous salts; soluble. CHLORIDE Cl. Co, 60H, in ruby-red octahedra. NITRATE (NO), O.Co, 60H2, deliqueseent, red mass. Insoluble salts. Cobaltous carbonate 3[CO(O2Co)],2OH2. Always precipitated as basic earbonate. Cobaltous arsenate As₂O₅(OCo)₃,80H₆ is "eobalt bloom." Cobalt imparts a deep blue tint to borax fused on a loop of platinum wire.

Co is estimated in the metallie form, and as Co₃O₄, eorre-

sponding to 73.34 per cent. of eobalt.

XXII. Nickel Ni = 58.8.

Never native. Dvad. Discovered by Cronstedt in 1751. Analogous to, and almost always associated with, Cobalt. Hard, lustrous, white, tenacious metal. Sp. gr. 8.8. Fused in windfurnace. Magnetic, but loses its property at 350° C. Not easily attacked by acids, except by NO2OH. Prep. from NICKEL OXALATE $C_2O_2(O_2Ni)$ in a wind-furnaee = $2CO_2 + Ni$. Niekel is now deposited by electrolysis upon articles of iron, steel, eopper, brass, &e. The alloy of German silver Cu, Zn, Ni, important. Chief ores of nickel are: Nickel arsenide As, Ni, or "Kupfer-niekel." Nickel di-arsenide As, Ni: by heat in elose vessels into As and As, Ni2. Nickel arsenio-sulphide AsNiS or nickel-glanee. "Speiss," obtained as a fused product in making "smalt" (see Cobalt) is mainly, fused Kupfer-nickel as far as Nickel is concerned. The separation, roughly, of the Co from the Ni, in the ehlorides, is accomplished by Cl₂OCa, which converts CoO into Co.O. and precipitates it, and then of the Ni as (OH), Ni by (OH)₂Ca. The reduction of the oxide by carbon is sufficiently simple. The separation is also effected by converting Co into potassium cobalti-cyanide and precipitating Nickel Cyanide (CN)₂Ni by ClII. One basic oxide. Nickel oxide NiO = 74.8. Olive-green. By igniting the carbonate out of contact of air. Hydroxide (OH)₂Ni, bulky light-green. Forms insoluble compounds with HOK, HONa, (HO)₂Ba, (HO)₂Sr. H₃N dissolves it to a blue solution. Salts are green. Nickel peroxide Ni₂O₃ is black. Hydrate (OH)₆Ni₂. Not basic. Thus: 2 (OH)₂Ni + Cl₂ + 2 HOK = 2 KCl + (OH)₆Ni₂. — Nickel sulphide SNi = 90.8, native as "Millerite." As black hydrated sulphide (OH₂)SNi, from solutions of nickel salts by SHH₄N. Subsulphide SNi₂. Disulphide S₂Ni. Soluble salts of nickel. Chloride Cl₂Ni,9OH₂ is green. Sulphate SO₄Ni,7OH₂, green rhombic prisms, isomorphous with SO₄Mg,7OH₂, SO₄Zn,7OH₂, SO₄Mn,7OH₂, and SO₄Fe,7OH₂. Soluble in 3 parts of water. Nitrate (NO₂)₂O₂Ni. Insoluble salts. Carbonate of nickel 3 [CO(O₂Ni)], 2 OH₂. Basic carbonate always precipitated. Nickel cyanide C₂N₂Ni, apple-green.

The nickel salts impart a reddish-yellow color to the borax

bead.

Nickel is estimated as NiO, containing 78.67 per cent. of Ni.

XXIII. Chromium Cr = 52.2.

A pseudo-triad metal in its chromic salts. Never native. Discovered by Vauquelin in 1797. Steel-grey. More intractable than Platinum. Sp. gr. 6.81. Insoluble, even in aqua regia. Prep. By strong ignition of Cr₂O₃ with Charcoal, in a wind-furnace. Or, by passing the vapor of sodium over redhot chromium chloride: $Cl_6Cr_2 + 3Na_2 = 6ClNa + Cr_2$. Two basic oxides, and one intermediate. 1. Chromous oxide CrO, only known as hydroxide (OH)2Cr. Brown, which absorbs O and becomes hydrate of Chromous-chromic oxide Cr0, Cr203, aq. Powerful base: forms chromous salts of pale-blue color, which absorb O. 2. Chromic oxide, $Cr_2O_3 = 152.4$. Greon, isomorphous with Al₂O₃, Mn₂O₃, Fe₂O₃ and substitutes Al₂O₃ in alums. Coloring-matter of the emerald, chlorite, pyrope, serpentine, &c. Employed as a green color for porcelain and glass. As hydroxide (OH), Cr2,4aq. of light-blue color. Salts green and uncrystallizable; violet and crystallizable. Prep. By heating Ammonium Chromate CrO₄(NH₄)₂. Or, crystalline, by heating potassium dichromate. "Chrome ironore" or Ferrous-chromic oxide FeO, Cr2O3, is the chief ore of chromium, corresponding to magnetic oxide of iron, Cr2O3 displacing Fe₂O₃. In octahedra and massive. 3. Chromic anhydride CrO3, in brilliant, dark-erimson, deliquescent prisms. Fuses at 200° C., and looks black. By further heat into 2(CrO₃, $Cr_2O_3) + 3O_2$, and then into Cr_2O_3 and $3O_2$. From $F_6Cr + 3OH_2 = 6FH + CrO_3$. Chromic acid $CrO_2(OH)_2$ in solution. Chromates,—Alkaline chromates soluble in water. Potassium DICHROMATE $CrO_2(OK)_2, CrO_3$ in 4-sided tables of red colour. Potassium chromate $CrO_2(OK)_2$ in yellow prisms, isomorphous with $SO_2(OK)_2$. Lead chromate $CrO_2(O_2Pb)$ forms "chrome-yellow." DIBASIC LEAD CHROMATE $C_1O_2(O_2Pb)$, PbO is almost scarlet. Silver chromate $CrO_2(OAg)_2$ is dark-red. So that the name, Chromium, from Χρωμα, color, is welldeserved. When chrome-iron-ore is calcined with mixed CO(OK)₂ and NO₂OK, the product when treated with water gives up potassium chromatc, the starting-point of all the preparations. 4. **Perchromic acid** Cr_2O_7,OH_2 or $Cr_2O_6(OH)_2$. Blue and unstable. Formed by addition of O_2H_2 to solution of CrO₂(OH)₂. Chromic sulphide S₃Cr₂, black, shiny scales. By S₂C over ignited Cr₂O₃. Chromic hydrate is precipitated by ammonium sulphide from solutions of chromic salts, soluble with green color in HOK. Chromium nitride Cr₂N₄, chocolatebrown, By heating Cl₆Cr₂ in dry H₃N. Salts of chromic, CHROMIC CHLORIDE Cl₆Cr₂, pale-violet scales. Volatile, Prep. ${}_{2}\text{Cr}_{2}\text{O}_{3} + 6\text{C} + 6\text{Cl}_{2} = 6\text{CO} + {}_{2}\text{Cl}_{6}\text{Cr}_{2}$. [Chloro-chromic acid ${}_{2}\text{Cr}_{2}\text{Cl}_{2}$, a dark-red, fuming liquid, of sp. gr. 1.92. Boils at 116°. 8 C. By distilling ClNa with CrO2(OK)2, CrO3 and SO₂(OH)₂. It is chromic anhydride in which Cl₂ substitutes O. Decomposed by 2OH2 into CrO2(OH)2 + 2ClH. neither Br nor I forms a similar compound, it is also a test for a chloride.] Chromic fluoride F_vCr₂. Blood-red liquid. Chromic sulphates. Insoluble, red: (SO₄)₃Cr₂. Soluble, green, uncrystallizable (SO₄)₃Cr₂,5OH₂. Solnble, violet, crystallizable $(SO_4)_3Cr_2$, 15 OH_2 . Potassium-chrome-alum $(SO_4)_4K_2Cr_2$, 24 OH_2 . Amethystine. Chromic nitrate (NO₃)₆Cr₂. Green. Chromium oxide imparts deep-green color to fused borax. It is estimated as Cr₂O₃ which contains 68.63 per cent. of Chromium.

[XXIV. Uranium U = 120.

Never native. Discovered by Klaproth in "Pitchblende," which consists mainly of uranous-uranic oxide, UO, U_2O_3 . It is steel-grey, slightly malleable, and not oxydized at ordinary temperatures; but burns beautifully when strongly heated, Sp. gr. 18.4. Diamagnetic. Analogous in its chemical relatious with Fe and Mn. Prep. by heating uranous chloride with potassium: $Cl_2U + K_2 = 2ClK + U$. Two basic and two intermediate oxides. I. Uranous oxide UO = 136. Forms green salts with a tendency to oxydize. Uranous chloride, Cl_2U , green, deliquescent octahedra: volatile. Prep. by

heating the oxide with charcoal in a stream of Chlorine. 2. Di-uranous-uranic oxide 2UO,U₂O₃, by igniting uranic nitrate, or heating UO to redness in air. Black: used in painting china. 3. Uranous-uranic oxide UO,U₂O₃, by heating the di-uranous-uranic oxide moderately in a current of air. No salts. Chief constituent of Pitchblende. Sp. gr. 7.31. 4. Uranic oxide U2O2, as a brick-red powder, by heating U2O3, 20H₂ to 300° C. Behaves like a base and a radiele. Salts of vellow color. Imparts vellow color to glass. 2NO, U,O,, 60H, in long, striated prisms of yellow color is the nitrate, perfectly soluble in ether. UO, or uranyl behaves like a metal. On addition of an alkali, uranate of the metal 2U2O3,OK2,3OH2 is precipitated of yellow color. Uranyl chloride, $Cl_2U_2O_2$, by passing Cl_2 over uranous oxide. Sulphides. SH_2 gives no precipitates. But ammonium sulphide gives a black precipitate with uranous, and a yellowish-brown with uranic salts. "Uranite" is Calcium di-uranyl phosphate 2 PO,,2U,O,,Ca,8OH,.. "Chaleolite," is 2PO,,2U,O,,Ĉu,8ÔH,,.]

Metals more or less allied to Tin.

	Symbol.		At. weight.
Stannum.	. Sn	=	118.0
Titanium	. Ti	=	50.0
Zirconium	. Z r	=	89.5
Thorinum	. Th	=	231.5

XXV. Stannum or Tin Sn = 118.

Tetrad metal, not found native. Very white and lustrous; mallcable, but little duetile. Sp. gr. 7.292. Emits a peculiar crackling sound when bent. Melts at 228° C. Tarnishes slowly and quite superficially. Crystalline tin in "moirée métallique." When strongly heated in air, burns into Stannic oxide SnO₂, its only ore. ClH dissolves it slowly as Stannous chloride; boiled with sulphuric acid, into Stannic sulphate, and tin is changed into Metastannic acid by NO₂OH. Alloys. Britannia metal. of equal parts of Sn, Brass, Sb and Bi. Pewter, of 4 parts of Sn, and 1 part of lead. Fine solder, 2 parts of Sn to I of Pb. Common solder of equal parts of Su and Pb. Course solder of 2 of Pb to 1 of Sn. Amalgams.—see Hg, p. 74. Two oxides. 1. Stannous oxide SnO = 134. Black, erystalline needles. By boiling Hydroxide 0H2,28n0 with HOK insufficient to re-dissolve it. Powerful base. Rapidly absorbs O, and becomes SnO_2 . Hydroxide is white, and very soluble in HOK and HONa. 2. Stannic oxide $SnO_2 = 150$. White. Native as "tin-stone." As alluvial deposit, known as "stream tin;" as constituent of granite and slate rocks, as "mine tin." In Cornwall, Saxony, Bohemia, New Zealand and Malaeea. Metallurgy. From Tin-stone SnO2 by charcoal or anthracite. Mine-tin contains SAsFe as well as S₂FeCn and much SiO₂. By eareful roasting, much of the As is volatilized as As₂O₂, and S as SO. Lime CaO, is added to form a slag with SiO. Further submitted to liquation process, pure tin melts first, and may be removed: the impure or "block tin" contains eertain alloys in small quantities. Stannic acid SnO(OH), or H₂SnO₃, white, gelatiuous precipitate, obtained by adding H₃N to solution of Cl₄Sn, or a quantity of ehalk insufficient for its entire decomposition. Stannates. SnO(OK), 3OH, SnO(ONa), 3OH2. So then stannie hydroxide behaves also like an acid. It is insoluble in H₃N. Heated to 140° C. into meta-stannic acid 5SnO₂,H₂O₄OH₂ or H₂Sn₅O₁₁,4aq., which is however most easily prepared by action of nitrie acid upon the metal: it forms insoluble compounds with ClH. Meta-stanuates are not erystallizable. Sulphides. Stannous sulphide SSn = 150. Blnish-grev. Fusing Sn and S together. As brown hydrate by SH₂ into solution of Cl₂Sn. Soluble as S₂Sn in S₂(NH₄)₂. Stannic sulphide S₂Sn = 182. Known as "Mosaie Gold," in bright yellow flakes. As yellow hydrate by SH, into Cl. Sn in solution; soluble in SHH, N. Stannous chloride Cl.Sn,2H,O in prisms. Soluble in ClH. By water into 2ClH and STANNOUS OXY-CHLORIDE CloSn, SnO, 2OHo. By boiling CloSn with ferrie hydrate, ferrous chloride is obtained in solution, and stannous stannate SnO, SnO, as a grey hydrate. 2Cl₂Sn + Fe₂O₃ = 2Cl₂Fe + Sn0,Sn0₂. Rednees mereurie chloride into merenrous chloride and mereury. a. 2ClaHg $+ \text{Cl}_2\text{Sn} = \text{Cl}_4\text{Sn} + \text{Cl}_2\text{Hg}_2$. b. $\text{Cl}_2\text{Hg}_2 + \text{Cl}_2\text{Sn} = \text{Cl}_4\text{Sn} + \text{Hg}_2$. Stannic chloride Cl, Sn, 5OH2, in rhomboids. By adding aqua regia to stannons chloride: praetically Cl₂Sn+Cl₂=Cl₄Sn. Also: 2Cl₂Hg + Sn = Cl₄Sn + 2Hg. Purple of Cassius. See Gold, p. 75. Stannous fluoride F.Sn, in shining prisms. Stannic fluoride F.Sn, only known in fluo-stannates. Thus: F,Sn,2FK,OH2 is isomorphous with silieo-fluoride, titano-fluoride, zircon-fluoride of potassium. Tin compounds easily reduced on charcoal in blowpipe-flame. It is estimated as STANNIC OXIDE . SnO2, which eontains 78.66 per eent. of tin.

[XXVI. Titanium Ti = 50.

Tetrad element, never native. Discovered by Gregor in 1791. Prismatic crystals and a dark-green powder. Sp. gr. 5.3. Burns magnificently in oxygen. *Prep.* of Ti. Cl₄Ti + 2Na₂ = 4ClNa + Ti. Great affinity for nitrogen. Ti₃N₄ resembles

eopper in color. $C_2N_2Ti_3N_2Ti_3$ in eopper-eolored cubes in certain slags from blast-furnaces. Three oxides. r. Titanous oxide TiO, black powder, but little known. 2. Titanic anhydride, $TiO_2 = 82$. Constitutes the chief ore. "Rutile," "Brookite," and "Anatase" are TiO_2 . "Meuaceanite," and "Iserine," consist of ferrous titanate. Yellowish-white, and after ignition only dissolved by FH. Like SiO_2 , soluble and insoluble modifications. Solution of titanic acid in ClH digested with Zn, gives a violet solution, which on addition of H_3N in excess deposits: 3. Titanous Titanite, TiO_2 , or Ti_2O_3 . TiO_2 after fusion with $SO_2(OH)(OK)$, soluble. TiS_2 in green scales. Titanic chloride Cl_4Ti , fumiug, volatile liquid, resembling $SnCl_4$. Titanic fluoride F_4Ti , colorless, fuming liquid, by water into oxy-fluoride and hydrogen fluo-titanate ${}_2FH, F_4Ti$. Titanium is estimated as TiO_2 .]

[XXVII. Zirconium Zr = 89.5.

Tetrad metal, never native. Resembling Si and Ti. A black amorphous powder, assuming some polish under the burnisher. Burns brilliantly when heated into Zircon-oxide $ZrO_2=121.5$. Crystalline Zr resembles antimony in appearance, and only burns in oxyhydrogen. Dissolved with ease by FH, evolving H, and forming hydrogen fluo-zirconide ${}_{2}FH,F_{4}Zr$. Prep. of Zr: from potassium fluo-zirconide ${}_{2}FK,F_{4}Zr+2K_2=6FK+Zr$. S₂Zr, brown. Zirconium oxide $ZrO_2=121.5$. White, infusible. After ignition insoluble in acids. $OH_{2}ZrO_{2}$, gelatinous bulkywhite, insoluble in caustic alkalies. When neutral solutions of its salts are boiled with one of potassium sulphate, a sparingly soluble Zirconium subsulphate separates. SiO₄Zr is found as "Zircon" and "hyacinth." Cl₄Zr, in needles, soluble in water and in alcohol.]

[XXVIII. Thorinum Th = 231.5.

Tetrad metal, never native. Discovered by Berzelius in 1828 in "Thorite," a silicate. Grey powder acquiring lustre under the burnisher. Sp. gr. 7.7 to 7.9. Dissolves easily in NO₂OH; slowly in ClH. Burns brilliantly when heated to ThO₂. Prep. from Cl₄Th by 2K₂ = 4ClK+Th. Thornum chloride, Cl₄Th in white, shining crystals. Prep. ThO₂ + 2C + 2Cl₂ = Cl₄Th + 2CO. One oxide: Thornum oxide ThO₂, white and very heavy. Sp. gr. 9.402. Thornum and potassium sulphate (SO₄), K₄Th, 2OH₂ separates as a crystalline powder from mixed sulphates, and the hydroxide of thorinum is precipitated by HOK, and then ignited.]

[XXIX. Molybdenum Mo = 96.

Dyad, tetrad and pseudo-triad, never native. White, brittle, very infusible metal. Sp. gr. 8.62. Name from μολύβδαινα "a piece of lead." which its ore "Molybdenite" resembles. By roasting in air, So Mo or Molybdic sulphide, becomes Molybdic anhydride MoO3, and this is reduced by charcoal in a smith's forge in a crucible lined with charcoal. Three oxides: two basic. Molybdous oxide MoO, black. By action of H2 (Zn and 2ClH, and ClH) upon a molybdate: reduced to MoCl2 and precipitated as hydroxide by HOK. When heated in air, burns to Molybdic oxide MoO2. Is deep-brown, and insoluble in acids. Its hydroxide dissolves readily to red solutions. From MoO3 by reducing agents. By NO₂OH into Molybdic anhydride MoO₃ = 144. White crystalline powder, slightly soluble in water. As acid, not known in free state. MOLYBDATE OF LEAD MOO, Pb, native, in yellow quadratic plates. MoO2(OH4N)2, in colorless, square prisms. Solution used to detect traces of ortho-phosphoric acid; snspected liquid acidnlated with NO2OH, and molybdate added. The liquid becomes yellow, and on boiling, deposits yellow crystalline precipitate of phosphorie and molybdic acids, combined with H₂N(3 per cent. P₂O₅). Sulphides. MoS₂. MoS₃. MoS₄. Chlorides. MoCl₂. Mo₂Cl₆. MoCl₄. MoCl₅. Mo₂Cl₆ heated in absence of air into yellow MoCl₂ and brown MoCl₄. MoCl₅ by heating Mo in a stream of Chlorine, and this in a stream of H into Mo.Cl.

Molybdenum is estimated as S2Mo: contains 60 per cent. of

Mo.]

[XXX. Wolfram, or Tungsten W = 184.

Tetrad and hexad metal, never native. Iron-grey metal of sp. gr. 17.6. Burns, when heated, into WO₃. From WO₃ by charcoal in a smith's forge. Oxides. Tungstic dioxide WO₂, not basic. As a brown powder by heating WO₃ with H₂. Tungstic anhydride WO₃ = 232. Forms Tungstic acid WO₂(OH)₂,OH₂ and Metatungstic acid W₄O₁₁(OH)₂. WO₃ straw-yellow powder. From "Scheelite" WO₄Ca by NO₂OH. The common mineral, "Wolfram," is WO₄Mn,3WO₄Fe. Sodum tungstate is sometimes added to starch to render stiffened fabrics incombustible. Chlorides. WCl₄ and WCl₆ are volatile. Sulphides S₂W, blnish-black needles. S₃W a powerful snlphuraeid. Sulpho-tungstates. Thus: S₄WK₂.

Tungsten is weighed as WO3: contains 79.31 per cent. of W.]

	Symbol.		At. weight.
Stibium .	. Sb	=	122.0
Arsenicum	. As	=	75.0
Bismuth .	. Bi	=	210.0
Vanadium	. V	=	51.3
Niobium .	. N b	=	94.0
Tantalum	. Ta	=	182.0

XXXI. Stibium or Antimony Sb = 122.

A triad and pentad element. Brilliant, bluish-white metal: flaky, crystalline (in rhombohedra, isomorphous with As), and so brittle that it may be pounded. Sp. gr. 6.7 to 6.8. Melts at 450° C. Burns brilliantly with formation of Antimonous OXIDE Sb₂O₃. By strong ClH, dissolves slowly as Cl₃Sb. NO2OH into METANTIMONIC ACID SbO3H. Takes fire in Cl: burns to Cl_3Sb . Chief ore "Grey antimony ore" S_3Sb_2 . Prep. of Sb. $2 Sb_2O_3 + 3C = 3CO_2 + 2Sb_2$. Alloys. "Type-metal" consists of 2 parts of Pb, one part of Sn and I of Sb. "Britannia metal "sometimes of r part of Sb and 9 parts of Sn. Antimonide of Zinc Sb, Zn, may be used for making Stibine. Antimonous hydride or Stibine H₃Sb = 125. Colorless gas, burning with greenish flame to water, and antimonous oxide. With limited supply of air, burns into water, and Sb. Heated in a tube, into H. and a brilliant crust of Sb. The erust is easily soluble in (H₄N)₂S₂, and separates on evaporation as S₃Sb₂. Passed into 3NO₂OAg, into 3NO₂OH + SbAg₃. Prep. from any eompound in presence of nascent H: $Cl_3Sb + 3H_2 = 3ClH + H_3Sb$. Sb₂Zn₃ + 6ClH = 3Cl₂Zn + 2H₃Sb. Sb with Chlorine. Anti-MONOUS CHLORIDE Cl₃Sb = 228.5. Deliquescent mass, fuses at 72° C., and boils at 223° C. Decomposed by water into ANTIMONOUS OXY-CHLORIDE CIOSb. ClaSb + OH2 = 2ClH + Closb. Prep. of Cl_3Sb . $a. S_3Sb_2 + 6ClH = 3SH_2 + 2Cl_3Sb$. b. S₂Sb₂ + 3Cl₂Hg = 3SHg + 2Cl₃Sb. "Butter of antimony." Antimonic chloride Cl₅Sb = 299.5. Volatile, colorless liquid. solid below o° C. By OH₂ into 2 ClH + antimonic oxychloride Cl. OSb. By excess of water into ClH and ORTH-ANTIMONIC ACID SbO(OH)₃. Thus: Cl₅Sb + 4OH₂ = 5ClH + SbO(OH)₃. In the same manner by SII2 into SULPHANTIMONIC CHLORIDE SCl₃Sb. Prep of Cl₅Sb. From Cl₃Sb + Cl₂ = Cl₅Sb. [ANTI-MONOUS BROMIDE BraSb. Fuses at 90° C., and boils at 270° C. I_3Sb in red tables. By $OH_2 = 2IH + IOSb$. F.Sb.] Sb and Sulphur. a. Antimonous sulphide $S_3Sb_2 = 340$. In granite or slate rocks. In 4-sided, transversely-striated prisms, as "Stibuite." Blue or Bengal lights consist of NO,OK 3 parts, \$ 2 parts and S₃Sb₂ 1 part. When roasted in air, into a mixture of S₃Sb₂ with O₃Sb₂. In making antimony, after roasting, CO(ONa), has to be added as well as chargoal for the reduction

of Sb_2O_3 . Thus: $S_3Sb_2 + 3CO(ONa)_2 = 3SNa_2 + Sb_2O_3 + 3CO_2$. Then: ${}_{2}\mathrm{Sh}_{2}\mathrm{O}_{3} + {}_{3}\mathrm{C} = {}_{3}\mathrm{CO}_{2} + {}_{2}\mathrm{Sh}_{2}$. $\mathbf{S}_{3}\mathrm{Sh}_{2}$, of a beautiful orange color, may be obtained by precipitation: 3SH2+2Cl3Sb=6ClH+ S₃Sb₂. Thus, too, may SH₂ be manufactured. S₃Sb₂ is insoluble in ammonium carbonate: S₃As₂ is soluble. Sulph-antimonites. Mineral kermes is 2S₃Sb₂, Sb₂O₃. Action of CO(OK)₂ on S_3Sb_2 : 6[CO(OK)₂] + 3OH₂ + 3S₃Sb₂ = 6[CO(OH)(OK)] + 3SK₂ + 2S₃Sb₂,Sb₂O₃. Antimonous oxy-disulphide S₂OSb₂, is found as red antimony ore in oblique rhombic prisms. b. Antimonic sulphide $\mathring{S}_5Sb_2=404$. Orange-red. Forms SULPH-ANTIMONATES with positive sulphides. Prep. 2Cl₅Sb₂ + 5SH₂ = S₅Sb₂ + 10ClH. Also called "Snlphantimonic anhydride."—Sb and Oxygen. I. Antimonous oxide Sb₂O₃ = 292. "White antimony ore" in prisms. Grey-white powder, yellow on heating, soluble in CIH and in TARTARIC ACID C₂H₂(OH)₂(COOH)₂. Basic properties. As hydroxide by pouring Cl₃Sb into a boiling solution of sodium carbonate. Very soluble in HOK. Burns when heated in air into ANTI-MONOUS ANTIMONATE Sb₂O₃, Sb₂O₅ = Sb₂O₄. [METANTIMONOUS ACID SbO(OH), is prepared by pouring Cl₃Sb into a cold solution of sodinm carbonate: ${}_{2}\text{Cl}_{3}\text{Sb} + \text{OH}_{2} + {}_{3}\text{CO(ONa)}_{2} = 6\text{ClNa}$ + 3CO₂ + 2SbO(OH). Metantimonites. By heat at 100°: 2 SbO(OH) = OH₂ + Sb₂O₃.] 2. Antimonic anhydride Sb₂O₅ Pale-yellow, tasteless, insoluble powder. by oxydizing Sb with NO2OH, washing and heating below redness. Loses oxygen at bright red-heat, and changed into antimonous antimonate Sb2O3, Sb2O5. Antimonic acid SbO3H, can be obtained by fusing CO(OK)2 with Sb2O5 = CO2+ 2Sb03K, and decomposing by ClH. By heat (2) ANTIMONIC ACID Sb03H into antimonic anhydride and water. Antimonic acid also called met-antimonic acid from its analogy to metaphosphoric acid. Pyr-antimonic acid Sb₂O₃(OH)₄ = H₄Sb₂O₇, is Frémy's met-antimonic acid. From Sb₂O₃(OK)₂(OH)₂ by 2ClH = 2ClK + Sb₂O₃(OH)₄. DI-POTASSIUM HYDROGEN-PYRAN-TIMONATE precipitates Na2 salts as insoluble Sb2O3(OH)2(ONa)2.

Antimony compounds yield ${\bf Sb}$ in brittle globules when heated on charcoal in blowpipe-flame, white vapors clouding the charcoal. Reinsch's test applicable: solution acidulated with ClH and boiled, gives a metallic deposit oxydized and dissolved by ${\rm Mn_2O_6(OK)_2}$, and precipitated in acidulated solution by ${\rm SH_2}$

as orange-coloured S3Sb2.

Arsenicum As = 75 (see p. 29).

XXXII. Bismuthum Bi = 210.

A triad and pentad element, chiefly native in quartz: extracted by fusion. Crystalline, and of exceeding beauty. Reddish-

white hue. Sp. gr. 9.79. Melts at 264° C. Most diamagnetic of all metals. Burns in Cl to Cl₃Bi, and when strongly heated, with bluish flame. Easily dissolved by NO,OII, somewhat diluted. Alloys. "Fusible metal" consists of 8 parts of Bi, 5 parts of Pb and 3 of tin: it melts at 98° C. Bismuthous chloride ClaBi = 316.5. Fusible, volatile, deliquescent. By water, into OXY-CHLORIDE Clobi. Thus: Cl₃Bi + OH₂ = 2ClH + ClOBi. "Pearl-white" is 2ClOBi,OH₂; insoluble in tartaric acid. *Prep.* of Cl₃Bi. Also, by distilling Bi with mercuric chloride: Bi₂ + 6Cl₂Hg = 3Cl₂Hg₂ + 2Cl₃Bi. [Bismuthous bromide Br₃Bi. IODIDE $I_3Bi.$] Oxides: one basic. I. BISMUTH OXIDE Bi_2O_2 ; velvet-black. Burns into Bi_2O_3 when heated in the air. 2. Bismuthous oxide $Bi_2O_3 = 468$. Yellow powder, fusible at a redheat. By heating nitrate to redness. Hydroxide Bi_2O_3 Horizontal Bi_2O_3 , OH_2 . insoluble in KOH and in H_3N . BISMUTHOUS NITRATE (NO₂)₃O₃Bi,5OH₂, transparent prisms obtained by dissolving Bi in NO₂OH. Poured into water, mainly into NO₂OH, and BASIC BISMUTH NITRATE (NO2)303Bi,Bi,03,30H2. Known as "magistery of bismuth." Sometimes a larger proportion of Bi. NO₂0H,Bi₂O₃. BISMUTHOUS PHOSPHATE POO₃Bi, insoluble in dilute nitric and acetic acids. 100 parts contain 23.28 parts of P_2O_3 . 3. BISMUTHIC ANHYDRIDE Bi_2O_3 . Brown powder, obtained by heating bismuthie acid BiO2OH to 132° C. BISMUTHIC ACID BiO₂OH or HBiO₃ red powder. Obtained by passing Cl through solution of HOK containing suspended Bi_2O_3 . Thus: $Bi_2O_3 + 2Cl_2 + 4KOH = 4ClK + OH_2 + 2HBiO_3$. Bismuth and S. BISMUTHOUS SULPHIDE $S_3Bi_2 = 516$. Native as "Bismuth-glanee" in needles isomorphous with S_3Sb_2 . Sp. gr. 6.4. Precipitated as S₃Bi₂ of brown color by SH₂ in acid solutions, insoluble in SHH₄N.

Bi is estimated as Bi₂O₃, containing 88.74 per cent. of metal. The metal easily obtained as a brittle bead, on chargoal, in

blowpipe-flame.

[XXXIII. Vanadium V = 51.3.

Pentad and triad metal, never native. Discovered in 1830 by Sefström. The metal, as obtained by Roseoe by prolonged ignition of Cl₂V in H₂ gas, is erystalline and of silvery lustre. It burns vividly in flame, forming V_2O_5 . Insoluble in ClH. Burns in Cl gas to VCl₄. Analogous to N, it forms five oxides. V_2O , V_2O_2 , V_2O_3 , V_2O_4 , V_2O_5 . Vanadum dioxide V_2O_5 is obtained by action of V_2O_5 upon the higher oxides. V_2O_3 by igniting V_2O_5 in a stream of H. V_2O_4 by oxydizing V_2O_2 or V_2O_3 . Vanadic anhydride $V_2O_5 = 182.6$. Reddish-yellow color, soluble in 1000 parts of water to light-yellow solution. Vanadates. Meta-Pyro- and Ortho-vanadates. Easily prepared

from AMMONIUM META-VANADATE VO.OH, N by heat. "Vanadinite" 3(VO4)2Pb3,Cl2Pb is isomorphous with "Pyromorphite" 3(PO₄)₂Pb₃,PbCl₂. **V** and **Cl. Cl₃V**, in shining tables, of peach-blossom color. By Cl₄V, Cl is evolved, and Cl₃V is obtained. Cl_2V from ${}_2Cl_3V + H_2$ through red-hot tube. V and N. VN. VN_2 . By heating VN to redness in a current of Cl_4V is obtained.

[XXXIV. Niobium or Columbium Nb = 94.

Tetrad element, never native. Found by Hatchett in 1801 in Columbite. In its affinities, resembles Phosphorus. Niobic ANHYDRIDE Nb₂O₅. Chloride Cl₅Nb. Fluoride F₅Nb. Oxy-FLUORIDE F.ONb.]

[XXXV. Tantalum Ta = 182.

Pentad metal, not native. In "Tantalite" and "Yttro-tantalite" by Ekeberg. Tantalic anhydride Ta, 05. Potassium TANTALIC FLUORIDE 2FK,F,Ta.]

					-			
	S	symbol.	, ,	At. weight		Sp. gr.		Fusing-point.
Plumbum		Pb	=	207.0	٠	11.380		325°. C.

Gallium		G	=	68.0	•	5.900	•	30°.1 C.
Indium		$_{ m In}$	=	113.4	٠	7.400	•	176°. C.]

XXXVI. Plumbum or lead Pb = 207.

Dyad and tetrad metal, never native. Bluish, soft, malleable, ductile, but little tenacious. Sp. gr. 11.38. Fuses at 325° C. Tarnishes slightly in damp air. Acted upon by soft water in presence of air and earbonic acid, crystals of COO, Pb, (OH), Pb being precipitated. Chlorides and nitrites in water also attack lead. Presence of sulphates in water best defence against lead-poisoning by water. Acidulated, no water fit to drink which darkens in the least degree on addition of SH₂. Lead oxydizes when melted. Dilute SO₄H₂, and ClH seareely act. NO,OH best solvent: 3Pb + 8NO,OH = 3[(NO₂)₂O₂Pb] + 4OH₂ + 2NO. Alloys, see Stannum, p. 61. Oxides: 4 known. One basic. 1. Suboxide Pb.O, black. 2. LEAD OXIDE or plumbic oxide PbO = 223. Powerful basic oxide. Yellow color. "Litharge" is fused oxide, "Massicot" unfused oxide. By the oxydation of lead in a current of air. HYDRATE 2PbO,OH₂ is white, alkaline to test-paper, as slightly soluble, and soluble in HOK: good test for Sulphur. 3. MINIUM or RED LEAD, a compound of 2Pb0, Pb0, is found native. Used as

a paint in "priming." Prepared by earefully heating lavigated lead oxide in a reverberatory furnace at 3 20° C. Decomposed by NO₂OH into lead nitrate and lead peroxide PbO₂. 4. Plumbic peroxide PbO₂ = 239. Native as "heavy lead ore," in ironblack, lustrous, 6-sided prisms. Absorbs SO, and changed into SO_2O_2Pb : test for SO_2 . Prep. of PbO_2 . $2PbO_1PbO_2+4NO_2OII = 2[(NO_2)_2O_2Pb] + PbO_2 + 2OH_2$. Also: $(C_2H_3O)_2O_2Pb + CO(ONa)_2 + Cl_2 + 2OH_2 = 2CINa + 2(C_2H_3O,OH) + OH_2 + CO(ONa)_2 + Cl_2 + 2OH_2 = 2CINa + CO(ONa)_2 + Cl_2 + CO(ONa)_2 + CO(ON$ CO₂ + PbO₂. Lead sulphide or plumbic sulphide SPb = 239, black. Precipitated in acid solutions by SH₂. As "galena" it is found both massive, as in cubes and dodeeahedra, of leaden hue, very lustrous and very brittle. Chief ore of lead. Metallurgy. SPb is first roasted. One portion remains unchanged SPb. Another portion oxydizes into LEAD SULPHATE SO₂O₂Pb, and yet another into SO, and LEAD OXIDE PbO. Now, when the furnaec doors are shut, the lead sulphate and the lead oxide react upon the unchanged lead sulphide, and give lead with sulphurous anhydride. Thus: SPb + 2PbO = SO₂ + 3Pb. Again: SO₄Pb + SPb = 2SO₂ + Pb₂. Soluble salts of PbO. Plumbum chloride Cl₂Pb, brilliant needles soluble in 135 parts of eold and 33 of boiling water. ClH precipitates soluble lead salts, when solution not too dilute. NITRATE $(NO_2)_2O_2Pb$, in white oetahedra, soluble in 8 parts of cold water. Heated to redness into: PbO + 2NO₂ + O (p. 10). ACETATE $(C_2\Pi_3O)_2O_2$ Pb, 3OH₂ is the "sugar of lead" of commerce. Right rhombie prisms, soluble in 2 of water. Basic acetate contains 2PbO,OH2. Insoluble lead-salts. Oxy-chloride 2Pb0,Cl,Pb, native as "Mendipite." Turner's Yellow 7Pb0, Cl₂Pb. Chlorosulphide 3SPb, 2Cl₂Pb, is precipitated white by insufficient SH₂ from Cl₂Pb. Bromide Br₂Pb, white, sparingly soluble. Iodide I₂Pb, yellow, soluble in boiling water, separating on cooling in golden scales. Cyanide C₂N₂Pb, white. Sulphate SO₄Pb = 303. White. Native as "lead vitriol" in colorless prisms and octahedra. Soluble in sulphurie acid: contained in "oil of vitriol" and precipitated white by water. Chromate Cro, Fb yellow. Native as "Lehmannite" in oblique prisms. Di-plumbic chromate PbO,CrO4Pb is vermilion-colored. Sulphite SOO2Pb, white. Carbonate COO₂Pb, native as "Cerussite" in needles. "White lead" (0H)2Pb,2C002Pb. Dissolves in NO2OH as lead-nitrate. Water must be added to ascertain whether residue of SO, Ba. Silicate Si(0₂Pb)₂. FLINT-GLASS 6SiO₂, K₂O, PbO. SILICATE and BORATE 3(SiOO2Pb), 2B2O3, 3PbO. Paste or Strass for imitating gems 8SiO2, K2O, 3PbO.

Lead-salts are poisonous. Antidote is Glauber salt, or Epsom salt, which precipitates SO₄Pb. Lead is weighed as lead sul-

phate SO, Pb containing 68.31 per cent. of metal.

XXXVII. Thallium TI = 203.6.

A monad metal, never native. Discovered by Crookes in 1861, by the spectroscope; a single brilliant green line nearly coincident with one of the inconspicuous lines of the Barium spectrum. θαλλδς, a budding twig. Between lead and silver in color, very heavy; of sp. gr. 11.862. Soft and malleable. Crystalline. Melts at 294° C. Tarnishes in air. Takes fire at 315° C. in oxygen and burns with green light. Combines also directly with Cl, Br, I, S and P. As chloride, but little soluble. HCl little action. With SO₄H₂ into H₂ and sulphate. Easily dissolved by NO₂OH. Forms alloys. *Prep.* of Tl, from sulphate by Zn, or electrolysis. Three oxides. Tl.O. THALLIUM OXIDE Tl.O, the only base. Is very soluble in water as THALLIUM HYDROXIDE HOTI, obtainable in pale-yellow prisms. Solution alkaline and absorbs CO2. Precipitates Mg, Mn, &c. Per-OXIDE TIO2, brown. THALLIUM SULPHIDE STI2, brownish-black, by SHH, N. Salts. CHLORIDE CITI. Little soluble in water, yellowish-white in color. Cl6Fe2,6CITI, red crystalline. 2CITI, Cl₂Pt. Cl₃Tl₂. Cl₂Tl. Cl₃Tl. CARBONATE CO(OTl)₂, in flattened prisms, soluble in 23 parts of water. NITRATE NO OTI, in prisms. Sulphate SO₂(OTl)₂, 6-sided prisms. Forms an alum, isomorphous with K, Na, Cs, Rb, L and Ag. (\$04), Tl, Al, 240Ho. Salts poisonous.

XXXVIII. Cuprum or Copper Cu = 63.4.

This metal is a dyad in its chief compounds, and is frequently found native. It has been long known, and derives its name from Cyprus. Found native in cubes, oetahedra, dendritic crystals and massive. Lustrous, mallcable, ductile and tenacious. It is of a rich red color. Next to silver, the best conductor of heat and electricity. Sp. gr. 8.952. Melts at 1091° C. Corrodes but slowly in air and quite superficially; rapidly in sea-water. Heated to redness, black cupric oxide and red cuprous oxide formed. Dilute ClH and SO4H22OH2 scarcely any action. NO, OH attacks it immediately: 8NO, OH + 3Cu = $3[(N0_2)_20_2Cu] + 4OH_2 + 2NO$. Boiled with SO_4H_2 : $Cu + 2SO_4H_2$ = 20 H₂ + SO₂ + SO₄Cu. Leaf copper takes fire in Cl. Burns with green color in oxy-hydrogen: salts impart green color to flame. Alloys. Brass Cu.Zn. MUNTZ METAL Cu.Zn. Speculum metal Cu, Sn. Bell-metal Cu, Sn. Bronze contains less tin. Copper and Hydrogen. Cuprous Hydride H2Cu2, by 2ClH into cuprous chloride Cl₂Cu₂. Thus: H₂Cu₂ + 2ClH = 2H₂ + Cl₂Cu₂. Remarkable illustration of the union of two atoms of the same element to form a molecule. At 70° C, into H2 + Cu2. Two basic oxides and one peroxide. 1. Cuprous oxide Cu2O = 142.8. Native as "ruby copper ore." Ruby color to glass. As yellow hydrate 4Cu₂O,OH₂. Reducing cupric salts, we obtain cuprous salts. Solutions colorless. 2. Cupric oxide CuO = 79.4. Black: by heating the nitrate to reduess. Only important oxide. Hydroxide (0H)₂Cu or CuH₂O₂, light-blue. Precipitated by HOK from soluble cupric salts. Becomes black, when boiled, through loss of water. Forms salts blue or green. Is soluble in oils and fats, which may become poisonous. CuO gives a green color to glass. In presence of sugar, on boiling a cupric salt with potassium hydroxide, cuprous oxide Cu2O is precipitated.—Tri-cupric nitride Cu₆N₂ as dark-green powder. Sulphides. 1. Cuprous SULPHIDE $SCu_2 = 158.8$. As "copper glance" in 6-sided prisms. It is the "fine metal" of copper-smelters. 2. Cupric sul-PHIDE SCu = 95.4. A rare mineral "Indigo copper," in flexible blue plates. As a dark-brown hydrate from cupric salts by SH, in acid solutions. "Copper pyrites" S2CuFe, is the chief ore of copper. Both massive, and in tetrahedra of brassy lustre. Metallurgy. I. Calcining. Fe chiefly oxydized: S volatilized as SO2. 2. Melting for coarse metal. Fe₂O₃ slagged off by SiO₂ as Si(O₂Fe)₂: "matt" (euprous sulphide) SCu₂ with some S₃Fe₂ remaining.

3. Re-calcining. All Fe oxydized. 4. Melting for fine metal. Remaining Fe₂O₃ slagged off: Cu₂S remaining. 5. Roasting SCu₂ and reduction. a. Cu₂S + 2O₂ = 2CuO + SO_2 . b. $2CuO + Cu_2S = SO_2 + 4Cu$. Blistered copper. 6. Refining. Fused in a reverberatory furnace; much Cu2O formed, reduced by charcoal, and poling with trunk of a young tree. Salts of copper. Cuprous Chloride Cl2Cu2, white. By dissolving Cu in Cl2Cu. Colorless solution; absorbs CO2. Cupric salts: soluble. Chloride Cl2Cu,2OH2, green deliqueseent needles. Soluble in alcohol. CuO + 2CIH = Cl₂Cu + OH₂. CUPRIO SULPHATE SO, O, Cu, 50H, in blue, doubly-oblique rhombs. Also with 70H₂, isomorphous with SO₂O₂Fe, 70H₂. Soluble in 4 of water. Anhydrous at 200° C., and white. Absorbs H₃N, and forms SO₄Cu, ; H₃N. At a red-heat into CuO + SO₂ + O. Insoluble in alcohol. With H₃N in solution, into SO₄, H₂NCu, H₄N, a beautifully blue salt. A test for Cu. NITRATE (NO₂)₂O₂Cu, 6OH₂ in blue rhomboidal prisms. ACETATE (C₂H₃O)₂O₂Cu,OH₂ in green, oblique-rhombic prisms. Insoluble cupric salts. Carbonate COO, Cu; not known. "Chessylite" (OH), Cu, 2COO, Cu, in oblique-rhombic prisms of blue color. "Malachite" (OH)₂Cu,COO₂Cu, beautifully green. Common malachite is used as an ore. By roasting into CuO, and by fuel into Cu. Cupric arsenite As(0H)0, Cu: "Scheele's Green." Cupric hydroxyl orth-arsenate AsO(OH)O2Cu, pale blue. "Verdigris" CuO, (C2H3O)2O2Cu,6OH2. Copper is precipitated by steel or iron with its peculiar bright-red color. It is weighed as CuO, 100 parts of which contain 79.85 parts of copper.

[XXXIX. Gallium Ga = 68.

Never native. A triad, intermediate between Aluminum and Indium. Discovered in 1875 by Lecoq de Boishaudran in a zine-blende. Hard white metal, malleable and ductile. Sp. gr. 5.9. Melts at 30°.1 C. Heated to redness, it only oxydizes upon the surface, and does not volatilize. Gallium oxide Ga₂O₃ is soluble in HOK, and Gallium is obtained by electrolysis of this solution. Gallium oxide substitutes Alumina in alum. Gallium hydroxide is white and soluble in excess. Gallium culloride Cl₃Ga is deliqueseent. Gallium sulphide S₃Ga₂ is white, and precipitated from its salts by SHH₄N.

Gallium gives a bright spectrum, exhibiting a brilliant line

and a fainter band in the violet. 'Watts' Chemistry.']

[XL. Indium In = 113.4.

Never native. A triad. Discovered in 1863 by Reich and Richter in the zinc-blende of Freiberg. Silver-white metal, malleable and ductile. Sp. gr. 7.421. Melts at 176° C. Less volatile than Cadmium. Heated to redness it hums with violet flame In₂O₃. Chloride Cl₃In, volatile. Sulphide S₃In₂ is yellow. Precipitated from neutral solutions by SH₂. Indium Oxide In₂O₃ yellow; Hydroxide is white, soluble in HOK, insoluble in H₃N. Zn and Cd precipitate Indium.

Two indigo-eolored lines, in the spectrum: one very bright and more refrangible than the blue line of Sr, the other fainter and still more refrangible, and approaching the blue line of

Potassium. 'Watts.']

XLI. Argentum or Silver Ag = 108.

Monad metal, frequently native, hoth crystallized and massive. The whitest and most lustrous of the metals. The best conductor of heat and electricity. Sp. gr. 10.53. Melts at 916° C. A nohle metal; does not tarnish in pure air, and its oxide is

reduced by heat alone. When heated it absorbs mechanically 22 times its bulk of oxygen, and "spits" on cooling. Great affinity for S. ClH does not dissolve it. NO2OH its great solvent: $Ag_0 + 3NO_0OH = OH_0 + NOOH + 2NO_0OAg$. Boiled with $SO_2(OH)_2$: $Ag_2 + 2SO_2(OH)_2 = 2OH_2 + SO_2 + SO_2(OAg)_2$. Alloys. Ag₃Cu₂. Our silver coinage contains 7.5 per eent. of copper and has a sp. gr. of 10.30. Assaying by curellation. English coin requires 51 times its weight of lead for eupellation: the base metal oxydizes and is absorbed by the cupel (bonecarth). Oxides. Three oxides: one basic. I. ARGENTOUS OXIDE Ag₄O, very unstable. 2. Argentic oxide Ag₂O, = 232, brown. Powerful base. From the Hydroxide HOAg at 60° C. Prep. $NO_2OAg + HOK = NO_2OK + HOAg$. Then: $2HOAg = OH_2$ + OAg₂. Soluble in H₃N. Slightly in water. At a low redheat into 2Ag₂ + O₂. Salts. 3. Peroxide Ag₂O₂. Darkgrey needles, by electrolysis of NO2OAg. Sulphides. ARGENTIC SULPHIDE SAg₂ = 248. Native as "silver glanee" in cubes and in oetahedra. Also in "red silver ore" S3Sb2,(SAg2)3. Is precipitated from its soluble salts even in acid solutions by SH2. Metallurgy. Ore containing SAg_2 , S_2Fe , S_2FeCu , is roasted with ClNa. $SAg_2 + 2ClNa + 2O_2 = SO_4Na_2 + 2ClAg$. $SCu + 2O_2 = SO_4Cu$. $2SCu + 4ClNa + 4O_2 = 2SO_4Na_2 + Cl_2 + 2Cl_2Cu_2$. ${}_{2}S_{2}Fe + 6ClNa + {}_{7}O_{2} = {}_{3}SO_{4}Na_{2} + Cl_{6}Fe_{2} + SO_{2}$. The mass, pounded, is mixed with water in a revolving cask, then serap iron added, and after sufficient time to convert ClaFe2 + Fe into 3Cl₂Fe; Cl₂Cu₂ + Fe into Cl₂Fe + Cu₂; SO₄Cu + into SO₄Fe + Cu, and lastly 2ClAg+Fe into Cl2Fe +Ag2; Mercury is added, and the amalgam formed with the reduced Ag and Cu, washed, strained and heated. Ag with Cu remains. Salts of silver: soluble in water. Argentic nitrate NO2OAg = 170. Square, colorless, anhydrous tables. Melts at 219° C. Cast into stieks; "lunar caustie." Very soluble in water. Also soluble in boiling alcohol. If made from copper containing silver, (NO₂)₂O₂Cu is first decomposed by heat, and OCu can be removed by filtration. Reduced by heat. Argentic sulphate SO₄Ag₂ = 312. Small rhombic prisms, soluble in 90 of cold water. Absorbs 4H3N. SILVER ALUM (SO₄)₄Ag₂Al₂,24OH₂. ACETATE C₂H₃O(OAg), thin silken needles. FLUORIDE FAg, very soluble. Potassium-ARGENTIC CYANIDE 2(CNK, CNAg), OH2 in rhombie prisms. Used in electro-plating. Soluble silver salts are irritant poisons: antidote ClNa. Insoluble silver salts. Argentic chloride ClAg = 143.5. Native as "horn silver" in cubes. Melts at 260° C. Easily reduced by Zn and Fe. Also by H, at a moderate heat. NB. Solutions of Cu and Ag can have Ag removed as insolublo ClAg, and the latter decomposed by Zn. 2ClAg + Zn = Cl₂Zn +Ag. When ClAg is fused with sodium earbonate: 4ClAg $+2CO(ONa)_2 = 4CINa + 2CO_2 + O_2 + 2Ag_2$. ClAg absorbs H₃N

largely, and gives it up on application of heat. It is also very soluble in liquor ammoniæ. Argentum bromide BrAg, yellowish; soluble in much liquor ammoniæ. Iodide IAg, yellow: insoluble in H₃N. All three insoluble in NO₂OH. Native as "iodite." Cyanide CNAg, white. Soluble in H₃N and in strong NO₂OH. Thiosulphate S₂O OAg)₂ white, decomposing into Ag₂ + S + SO₄H₂ with OH₂. Orthophosphate PO(OAg)₃, bright-yellow, soluble in H₃N and in NO₂OH. Pyrophosphate P₂O₃(OAg)₄, white. Metaphosphate PO₂OAg, white, soluble in H₃N and in NO₂OH. Arsenite As(OAg)₃, yellow, soluble in H₃N and in NO₂OH. Arsenate As(OAg)₃, liver-brown, and soluble in H₃N and NO₂OH. Borate BO(OAg) white. Chromate CrO₄Ag₂ crimson. The metal Silver easily obtained in globules. Precipitated from its solutions as silver chloride ClAg, 100 parts of which contain 75.26 of the metal. It is weighed as chloride.

XLII. Hydrargyrum Hg = 200.

A dyad metal, rarely native. The molecule of the vapor, equal two vols., contains only one atom like Zu, Cd, &c. A noble metal, which does not tarnish, and whose oxides are reduced by heat alone. Its name from ὕδωρ, water, and ἄργυρον, silver, from its fluid state and lustre like silver. Fluid above 38°.8 C. Sp. gr. 13.59. Boils at 357° C. Forms amalgams with the metals. AgHg. CuHg. ZngHg. PbgHg. FeHg. SngHg. Hydrogen chloride does not attack Hg. With SO4H2. 2SO4H2 + Hg = $SO_4Hg + 2OH_2 + SO_2$. With nitrie acid: $3Hg + 8NO_2OH =$ 3[(NO₂)O₂Hg] + 4OH₂ + 2NO. Combines directly with Cl, Br, I and S. Used for silvering mirrors, and for extracting An and Ag. Heated to 300° C., slowly into HgO. Sulphides. Mer-CUROUS SULPHIDE SHg, black, and unstable. From salts by SH₂. MERCURIC SULPHIDE SHg = 232 = 3 vols. Native as Cinnabar in hexahedral prisms: the chief ore. Vermilion is artificial SHg. It is precipitated black by SH, from its salts, insoluble in NO,OH. Metallurgy. a. By washing and collecting the metal. $SHg + O_2 = SO_2 + Hg$. b. SHg + Fe =SFe + Hg. $c. 4SHg + 4CaO = 4Hg + SO_1Ca + 3SCa$. ides; 2 basic. 1. MERCUROUS OXIDE OHg2 = 416, black, unstable. From $Cl_2Hg_2 + 2HOK = 2ClK + OH_2 + OHg_2$. Decomposed by light into $Cl_2Hg + Hg$. 2. MERCURIC OXIDE OHg = 216. Red erystalline powder. "Red oxide" from which O first prepared. Prep. also by decomposing (NO₂)₂O₂Hg₂ by heat. Ammonia upon mercuric oxide: MERCURAMINE HYDRATE N₂Hg₄(OH)₂,4OH₂. Yellowish-white, and decomposed by light. Absorbs CO2. Unites with acids to form salts. Salts. Mercurous. Soluble in water. MERCUROUS NITRATE (NO2)202 Hg2,20H2 in efflorescent prisms. ACETATE (C,H3O),O,Hg2, in silvery seales, soluble in boiling water. Insoluble in water. Mercurous chloride $Cl_2Hg_2 = 471 = 4$ volumes. "Calomel." In 4-sided prisms, or as a yellowish-white powder. By Limewater into "black-wash" Hg_2O . By H_3N into ClH_2Hg_2N . Thus: ${}_2H_3N + Cl_2Hg_2 = ClH_4N + ClH_2Hg_2N$; or ammonium ehloride in which Hg₂ substitutes H₂. Prep. of ealomel. By subliming a mixture of ${}_2\mathrm{ClNa} + \mathrm{SO}_4\mathrm{Hg}_2 = \mathrm{Cl}_2\mathrm{Hg}_2 + \mathrm{SO}_4\mathrm{Na}_2$. Bromide $\mathrm{Br}_2\mathrm{Hg}_2$. Iodide $\mathrm{I}_2\mathrm{Hg}_2$ green. By light into $\mathrm{I}_2\mathrm{Hg} +$ Hg. Chromate Hg.0,3CrO₄Hg₂. Soluble mercuric salts. Mercuric chloride Cl₂Hg = 271. "Corrosive sublimate." In needles soluble in 16 of cold and 3 of boiling water. Fuses at 265° C., and boils at 295° C. Violent aerid poison: antidote egg-albumen. Coagulates albumen, hence its use also in kyanizing timber. Forms double salts with ClK, ClNa, ClH₄N. Prep. of corrosive sublimate. By subliming a mixture of ${}_{2}ClNa + SO_{4}Hg = SO_{4}Na_{2} + Cl_{2}Hg$. "White precipitate" is Chloro-amide of mercury $ClH_{2}HgN$. Thus: ${}_{2}H_{3}N + Cl_{2}Hg =$ ClH₄N + ClH₂HgN. Chloro-sulphide Cl₂Hg, 2SHg, white and precipitated by SH, when Cl. Hg in considerable excess. Both chloro-amide and ehloro-sulphide of mercurie are insoluble in water. Bromide Br. Hg, erystalline. Cyanide C.N. Hg, rectangular prisms, soluble in 8 of water. By heat into Hg, C2N2, and paracyanogen. MERCURIC OXY-CYANIDE C.N. Hg, HgO, in needles. MERCURIC NITRATE 2[(NO2)2O2Hg],OH2. MERCURIC SULPHATE SO, Hg, white erystalline powder. Insoluble salts, Chloro-amide. Chloro-sulphide. Mercuric oxy-chlorides, by the action of CO(OH)(OK) upon ClaHg, or by boiling HgO with Cl₂Hg. ²Hg0,Cl₂Hg. ³Hg0,Cl₂Hg. ⁴Hg0,Cl₂Hg. iodide I2Hg = 454. Searlet, and readily soluble in excess of IK. Mercuric ammonium iodide IHg, N,OH, is brown. It is oecasioned by the use of Nessler's test (a solution of mereurie iodide in potassium iodide, to which potassium hydroxide has been added) to a liquid containing H₃N. Basic mercuric sulphate SO, Hg, 2HgO is yellow. "Mineral turpeth." Basic mercuric nitrate (NO2)202Hg,2Hg0,0H2, yellow. Salts of mercury are readily reduced to metallic state by Cu, or by heating the dry compounds with CO(ONa)2. Stannons chloride may be used (see Cl.Sn). The metal is weighed as mercury.

XLIII. Aurum Au = 196.6.

This triad metal is always found native, both massive and crystallized in cubes, octahedra and tetrahedra. In California, Australia, Ural Mountains, &c. Bright yellow, lustrous metal. of sp. gr. 19.34. The most malleable of all metals; gold-leaf of an inch in thickness. Inferior to Ag and Cu in conductivity. Melts at 1037° C. Untarnishable in air. A noblo

metal, as its oxide becomes metallie by heat alone. Only attacked by Cl, Br, I. $Au_2 + 2Cl_3 = 2Cl_3Au$. Standard gold is alloyed with 8.33 per cent. of Cu: alloy harder and more fusible than pure gold. Ag separated by "quartation ' process, i.e. fusion with Ag so as to reduce the gold to \(\frac{1}{4}\), and employing NO₂OH for solution of the Ag as NO₂OAg; gold left as a brown powder. Two chlorides. Aurous chloride ClAu = 232.1. Pale yellow, sparingly soluble powder, losing all its Cl at 200° C. Prepared from Cl3Au by heat at 175° C. Auric chloride Cl₃Au = 303.1. Red, deliquescent salt, by dissolving Au in aqua regia, and evaporation below 120° C. Solution orange, or yellow when dilute. By heat into $Cl_2 + ClAu$, and then into Cl and Au. Easily reduced by P_2 , Cu, Hg, Zn, Fe, &c. Also by SO₄Fe. Thus: $6SO_4Fe + 2Cl_3Au = Cl_6Fe_2 + 2[(SO_4)_3Fe_2] + Au_2$. Also by OXALIC ACID $C_2O_2(OH)_2$. Thus: $2Cl_3Au + Cl_3Au + Cl_$ 3C₂O₂(OH)₂ = 6ClH + 6CO₂ + 2Au. Also by ANTIMONOUS CHLORIDE Cl₃Sb. Thus: ${}_{2}\text{Cl}_{3}\text{Au} + {}_{3}\text{Cl}_{3}\text{Sb} = {}_{3}\text{Cl}_{3}\text{Sb} + \text{Au}_{2}$. Also by sulphurous acid SO(OH)₂. Thus: ${}_{2}\text{Cl}_{3}\text{Au} + {}_{3}\text{OH}_{2} +$ $_3SO(OH)_2 = 6ClH + _3SO_2(OH)_2 + Au_2$. Used as a test for tin. "Purple of Cassius" Au₂Sn, Au₆Sn₂, 40H₂. Two oxides. 1. Au-ROUS OXIDE Au₂0 = 409.2. Green powder; with H₃N "fulminating gold," By HOK from aurous ehloride. 2. AURIC OXIDE $Au_2O_3 = 441.2$. Brown powder. Or, as yellow hydrate Au₂O₃30H₂, if precipitated by Mg(OH)₂ from 2Cl₃Au, and excess of MgO removed by dilute NO2OH. At 245° C. into Au₂ + O₂. Properties of an acid. Aurates. Au0(0K),30H₂. Sulphides. Auric sulphide S.Au., deep yellow. By passing SH, through dilute Cl. Au. AUROUS-AURIC SULPHIDE SAU. S. Au. Black. Soluble in alkaline sulphides to sulphur salts. E.g. 4SAuNa, 2S, Na, Gold is used for staining glass ruby-red, and as "Burgos lustre" a double sulphide of Gold and Potassium, for gilding china. It is weighed as Gold.

XLIV. Platinum Pt = 197.1.

A tetrad metal, always found native, and as an alloy with Palladium, Osmium, Iridium, Rhodium and Ruthenium in the Ural Mountains, Brazil and Ceylon. Discovered by Wood in 1741. White lustrous metal, very malleable and ductile. Sp. gr. 21.53. Melts at 1460° C. A noble metal: its oxides, by heat, into Pt and O. Aqua regia dissolves it as Platinic ehloride, and it is precipitated from its solutions quantitatively, by ammonium ehloride as Ammonium-Platinio Chloride 2(ClH,N),Cl,Pt. By heat into 2ClH₄N + Cl₂ + Pt. Thus is "spongy platinum" prepared. Another form of more finely divided platinum, "platinum black," is obtained by boiling a solution of platinous chloride in strong HOK, and adding alcohol. In these conditions it

condenses O in its porces: "Doberciner lamp." Alloys. Lead and Bismuth to be avoided in vessels of platinum, or on platinum foil. Also phosphorus, or phosphates, with reducing agents. Chlorides. I. PLATINOUS CHLORIDE Cl. Pt = 268. Of olive color, insoluble in water. Crystallizable double salts with 2ClK, 2ClNa, &c. By heating Cl₄Pt at 235° C. as long as Cl₂ is expelled.

2. PLATINIC CHLORIDE Cl₂Pt = 339. Red-brown, deliquescent prisms. Unites with, 2ClH,Cl,Pt, 60H2. Also with, 2ClK,Cl,Pt: 2ClH, N,Cl, Pt. Also with, 2ClCs, 2ClRb, 2ClL. All of these salts sufficiently insoluble to enable us to determine the respective metals.—[Basic ammoniacal derivatives from the chlorides. PLATOSAMINE PtH₄N₂,OH₂. DIPLATOSAMINE PtH₁₀N₄,2OH₂. PLATINAMINE PtH₂N₂,4OH₂. DIPLATINAMINE HYDROCHLORIDE PtH₈N₄2ClH (base not isolated), &c.] **Oxides.** 1. Platinoùs Oxide PtO = 213. Black hydrate. From Cl₂Pt by 2HOK. 2. PLATINIC-OXIDE PtO2 = 229. As brown HYDRATE 2OH2, PtO2. Soluble in HOK. Salts well characterized. Sulphides. 1. Pla-TINOUS SULPHIDE SPt: black. 2. PLATINIC SULPHIDE S.Pt. Brown-black. Somewhat soluble in alkaline sulphides.

Platinum may be weighed, either as Pt, or as 2ClH, N, Cl, Pt

which contains 44.17 per cent, of the metal.

[XLV. Palladium Pd = 106.5.

A dyad metal, discovered by Wollaston in 1803. Occasionally native in cubes and hexagonal plates. Usually forms \frac{1}{2} to 1 per cent. of the Platinum ores. Pd may be separated from all metals except Pb and Cu, by C2N2Hg. Ignited, leaves Palladium. From palladium ores, after couversion into chlorides, and the removal of Platinic chloride by 2ClH4N, MERCURIO CYANIDE C, N, Hg precipitates PALLADIOUS CYANIDE C, N, Pd. In a solution containing the nitrates of Pb, Cu, Fe, and Pd, ferric and plumbic are precipitated by H3N, and the ammoniacal solution containing ammonia compounds of Cu and Pd, is precipitated by ClH; PALLADAMINE HYDROCHLORIDE Cl2H6N2Pd as a yellow, sparingly soluble salt is separated from which the metal is obtained by heat. White, hard and lustrous. Noble metal: its oxides into metal and oxygen by heat. Sp. gr. 11.8. Melts at 1360° C. Dissolved by NO₂OH. Metallic palladium takes up 982 times its volume of Hydrogenium, forming an alloy. From its increase in bulk by the absorption of H, which the Palladium undergoes when placed as the negative electrode in acidulated water, the density of the metal Hydrogenium is ascertained to be 0.733. Chlorides. 1. PALLADOUS CHLORIDE Cl₂Pd = 177.5. By evaporation of solution of Pd in aqua regia. Brown hydrate. With H_3N a series of basic compounds like those with Pt. Thus Palladamine PdH_6N_2O . 2. Palladic CHLORIDE Cl_4Pd . Only in solution. ${}_2ClK, Cl_4Pd$ in ruby-red erystals. Palladous iddies I_2Pd , a black powder. Palladous oyanide C_2N_2Pd yellow. Forms soluble double eyanides. Oxides: 3. Pd_2O . PdO. PdO_2 . Palladous oxide PdO = 122.5 is the chief oxide. Black powder. Also as hydrate by HOK from palladous salts. Sulphides: three. Pd_2S . PdS. Palladous sulphide PdO. Precipitating PdO by PdO.

Palladium, precipitated as cyanide, is weighed as Palladium.]

[XLVI. Rhodium Ro = 104.3.

[XLVII. Ruthenium Ru = 104.2.

A triad, never native but in an alloy of Os, Ir, Ru, and R. Discovered by Claus in 1845. Hard, brittle, most infusible metal. Sp. gr. 11.4. Oxydized when heated, or by fusion with NO₂OK. Three chlorides. RuCl₂. RuCl₃. RuCl₄. Sulphides. SRu. S₃Ru₂. S₃Ru. Oxides. RuO. Ru₂O₃. RuO₂. RuO₃. RuO₄.]

[XLVIII. Osmium 0s = 199.

Discovered by Tennant in 1803 in Osmium-Iridium-Ruthenium. Bluish-white metal of sp. gr. 21.4. Very infusible, Burns to Osmium tetroxide OsO_4 . From $OsO_4 + 8Hg + 8ClH = 4OH_2 + 4Cl_2Hg_2 + 0s$. From the pungent, irritating odor of OsO_4 , it has its name from $\delta\sigma\mu\eta$, smell. Four chlorides. Cl_0s. Cl_30s. Cl_40s. Cl_60s. Tetrachlorides Cl_40s. Red, crystalline, fusible deliqueseent sublimate. Five oxides. OsO. Os_0_3. OsO_2. OsO_3. OsO_4. Osmium tetroxide OsO_4 = 263. Colorless needles, very solnble in water. Vapor irritating and poisonous. SH_2 in HCl, precipitates black hydrated sulphide, S_4Os.]

[XLIX. Iridium Ir = 198.

Sometimes native. Discovered by Tennant in 1803. Usually as an alloy with Os. White brittle metal of sp. gr. 21.15.

From cClK,Cl4Ir, heated in a stream of H2; ClK removed by washing. Three chlorides. Cl2Ir. Cl3Ir. Cl4Ir. Three oxides. Iro. Ir203. Ir02. Three sulphides. SIr. S2Ir3. S2Ir. From the changes of color, owing to the rapidity with which the oxides pass into oue another, the name Iridium was given, from Iris.]

END OF INORGANIC CHEMISTRY.

ORGANIC CHEMISTRY.

Organic Chemistry is the Chemistry of Carbon compounds, Carbon being the most characteristic constituent of all vegetable aud animal matters. Thus, when any organized structure is heated out of contact with air, it blackens, owing to the presence of unburnt carbon. Most carbon compounds contain only a few elements. They consist either of Carbon and Hydrogen; Carbon and Oxygen; Carbon, Hydrogen and Oxygen; Carbon and Nitrogen; Carbon and Sulphur; Carbon, Nitrogen, and Hydrogen; Carbon, Hydrogen, Oxygen and Nitrogen, sometimes even of C, H, N and O with Sulphur and Phosphorus.

Many organic compounds are made by synthesis, in the same

way as are inorganie.

We have already learnt that the atoms of different bodies differ in their quantivalence (p. 2). As Hydrogen forms the most simple compounds, it is best adapted for ascertaining the quantivalence of other elements, of which those forming volatile hydrides can be divided into four groups:

1.
$$\frac{H}{H}$$
 $\frac{Cl}{H}$ $\frac{Br}{H}$ $\frac{I}{H}$ $\frac{F}{H}$ 2. $0\left\{\frac{H}{H} \text{ S}\left\{\frac{H}{H} \text{ Se}\left\{\frac{H}{H} \text{ Te}\left\{\frac{H}{H}\right\}\right\}\right\}\right\}$
3. $\frac{H}{H}$ $\frac{H}{$

Thus we find H, Cl, Br, I and F aro MONADS; O, S, Se and Te, DYADS; N, P, As and Sb, TRIADS; C and Si, TETRADS.

The smallest particle of such compounds consists of a coalition of atoms, called a molecule. As the densities of all gases and vapors are equal to half their molecular weights, equal volumes of different gases always contain the same number of molecules; so that any molecule, in the gascous or vaporous condition, oeeupies the same space as two parts by weight of hydrogen.

Carbon is a tetrad element; its most simple compound is METHANE CH4. By substitution of other monads, we obtain CH,Cl; CH,Cl2; CHCl3; CCl4. By replacing the monads by dyads, we obtain ${\bf CO}_2$; ${\bf CS}_2$; with triads, ${\bf CNH}$. When two atoms of carbon unite with each other, two out of the eight units of combining capacity saturate each other, so that the result is a hexad group; when three atoms of carbon are thus linked together, we obtain au octad group.

Of course Cl, Br, I, &c., may be substituted for one atom of Hydrogen, but O and N can only substitute respectively two and three atoms of Hydrogen. The monad groups (OH) and (NH₂) can replace one atom of hydrogen. Thus:

C H_3 **0H** is methane C H_4 in which **0H** substitutes **H**. C_2H_3 **0H** is ethane C_2H_6 in which **0H** substitutes **H**. C_3H_7 **0H** is propane C_3H_8 in which **0H** substitutes **H**.

So we have a number of compounds in a series, each of which differs from the next by \mathbf{CH}_2 ; homologous, analogy of constitution, with a difference in composition of \mathbf{CH}_2 , or a multiple of \mathbf{CH}_2 .

When the different members of a homologous series are submitted to similar chemical reagents, they furnish derivative series in which the homology is still preserved; such collateral series are called heterologous, e.g.:

When the successive terms of a series differ only by \mathbf{H}_2 we have an isologous series. Thus:

ethane C_2H_6 ethene C_2H_4 ethine C_2H_2 . Propane C_3H_8 propene C_3H_6 propine C_3H_4 propone C_3H_2

Each vertical column forms a HOMOLOGOUS, and each horizontal line an ISOLOGOUS series.

All hydrocarbons contain an even number of atoms of hydrogen, as a consequence of the tetrad character of the element carbon. Further, it follows that the sum of the atoms of monad

and triad elements, contained in the molecule of a earbon com-

pound, must also always be an even number.

Carbon compounds having the same percentage composition, but differing in their physical and chemical properties, are called isomeric. All true isomeric compounds contain the same number of carbon atoms linked together. Polymeric bodies are such as have the same percentage composition but different molecular weights. Ethene C₂H₄, propene C₃H₅, and buttene C₄H₈ are polymeric. Metameric bodies have the same percentage composition and the same molecular weights, e.g.:

$$N \begin{cases} C_3H_7 \\ H \\ H \end{cases} \qquad N \begin{cases} CH_3 \\ C_2H_5 \\ H \end{cases} \qquad N \begin{cases} CH_3 \\ CH_3 \\ CH_3 \end{cases}$$

Here we have C₃H₉N, constituting three metameric bodies in which different radieles are linked together by the same poly-

genie element.

Most carbon compounds are liquid or solid. The more volatile a substance, the more simple is its constitution. In homologous series the boiling-point must rise by each added CH₂; in some cases it does so with great regularity. In the normal alcohols there is a regular difference of 19°C. between each. Thus ETHYL ALCOHOL C₂H₃OH, boils at 78°.4; PROPYL ALCOHOL C₃H₇OH, at 97°; BUTYL ALCOHOL C₄H₉OH, at 116°C.

When the difference in the boiling-points of two bodies is considerable, it is possible, when mixed together, to separate them by fractional distillation: the more volatile body distils at a

nearly constant temperature.

The determination of the composition of earbon compounds is by organic analysis. A known weight of the body to be analyzed is burnt in contact with an easily reducible metallic oxide, generally cupric oxide. The Carbon is burnt into carbonic anhydride CO2, and the Hydrogen into water OH2. The resulting compounds are collected and weighed. Nitrogen is determined by heating with soda-lime and collecting the Ammonia HaN in ClH, and weighing as AMMONIUM PLATINIC CHLORIDE 2CIH, N, Cl, Pt. If the Nitrogen cannot be completely converted into H₃N, it must be separated in the free state, and collected over mercury. Oxygen is estimated by the loss. Compounds containing Chlorine, Bromine and Iodine are heated in a narrow combustion-tube with pure CALCIUM OXIDE. Sulphur and Phosphorus are determined by heating the earbon compound with Sodium Carbonate and Potassium nitrate, or even by OXYDATION with NITRIC ACID in sealed tubes. In both cases, the sulphuric and phosphoric acids are estimated by common analytical methods. In a similar manner are bodies treated which contain Arsenicum, Boron, Silicon, &c. In metallic salts

of organic compounds, ignition occasions either the separation of metal, of oxide, or of carbonate. The empirical formula of a compound is easily obtained by dividing the percentage composition by the respective atomic weights. Thus with carbonyl CO. It consists of:

Now $42.858 \div 12 = 3.571$, and $57.142 \div 16 = 3.571$. It is therefore obvious that the simplest formula for carbonyl is CO, composed of one atom respectively of Carbon and of Oxygen.

For determining the vapor-density, we ascertain either the weight of a given volume of vapor (Dumas' process), or the volume of a given weight of vapor (Gay-Lussac's).

I. Mono-carbon or Methane group.

Methane CH, = 16. Found as fire-damp and marsh-gas. Colorless, inodorous gas, little soluble, inflammable with searcely luminous flame. Sp. gr. 8. A mixture of CH4 + 2Cl2 explodes in sunlight to 4ClH + C. By diffused light into CH3Cl, CH2Cl2, CHCl3 and CCl4. Prep. p. 11. Also by nascent H, upon trichlormethane or chloroform. $CHCl_3 + 3H_2 = 3CIH + CH_4$. Again by $2OH_2$ upon zinc methide $Zn(CH_3)_2 = zinc$ hydroxide $Z_{\rm u}({\rm OH})_2 + CH_4$. Methane is the first of the paraffins C_nH_{2n+2} ; it is a saturated hydroearbon which cannot unite directly with Cl, Br, I and other monads. It may however take up any number of dyad elements or radicles, because such a radicle introduced into any group of atoms neutralizes one unit of equivalency, and adds another. Thus methane is the first of an homologous series of paraffins. CH₄CH₂ = $\mathbf{C_2H_6}$, or one atom of H displaced by CH₃. E.g. CH₄; C₂H₆, p. 91; C₃H₈, p. 100; C₄H₁₀, p. 104; C₅H₁₂, p. 106; C₆H₁₄, p. 108, &c. Methane may be deprived of a molecule of H2, and give rise to a dyad radicle, the first of an homologous series CH_2 ; C_2H_4 ; C_3H_6 ; C_4H_8 . a. Chloromethane or methyl chloride CH3Cl. Colorless gas, of sweetish taste, but little soluble in water. Burns with pale flame. Prep. 1. From methane, by Cl2 in diffused daylight. Also by distilling methyl alcohol with sodium ehloride and sulphuric acid. $CH_3OH + \dot{C}INa + SO_2(OH)_2 = SO_2(OH)(ONa) + O\dot{H}_2 + CH_3CI.$ Successively by chlorine into METHENE CHLORIDE CH2Cl2; ME-THENYL CHLORIDE CHCl3 and CARBONIC CHLORIDE CCl4. Methyl bromide CH3Br. Coloil ss liquid, boiling at 13° C. iodide CH3I. Boils at 43° C. Practically: CH3OH + IH = OH₂ + CH₃I. [b. Methene chloride CH₂Cl₂. Methene bromide

CH₂Br₂. Methene iodide CH₂I₂. By IH upon methenyl iodide.] c. Chloroform is TRICHLOR-METHANE or methenyl chloride CHCl3. Colorless, mobile fluid of sp. gr. 1.525 at 0° C. Boils at 63°.5 C. Of pleasant smell, and sweet taste. Little soluble in water; very, in alcohol and ether. By digestion with alcoholic potassium hydroxide, into 2OH, + 3ČIK + POTASSIUM FORMATE CHO(OK). By ammonia, in presence of KOH into 40H₂ + 3ClK + CNK. Solvent of I, Br, P, alkaloids, resins, &c. Great anæsthetic. Does not redden litmus or precipitate NO₂(OAg.) Sp. gr. 1.49 at 17° C. [Heated with NO2OH at 100° C. for some time, into methane-nitro-chloride or Chloropickin CNO2Cl3, a colorless liquid, exciting to tears.] Prep. By alkalies upon CHLORAL CCl₃COH. Thus: CCl₃COH + KOH = POTASSIUM FORMATE CHO(OK) + CHCl3. Also by boiling TRI-CHLORACETIC ACID CCl3, **COOH** with $2 \text{HOK} = OH_2 + CO(OK)_2 + CHCl_3$. Also by Cl₂ in presence of hydroxides upon methyl or ethyl alcohol: practically by distilling alcohol, water and chloride of lime. Probably first CHLORAL CCI₂COH, and 5ClH, and then the chloral by Ca(OH)₂ = CALCIUM FORMATE and chloroform CHCla. Methenyl bromide CHBr., Colorless liquid, odorous, like chloroform, of sp. gr. 2.9.; boils at 152°C. Methenyl iodide CHI3, in yellow tables, with odor of saffron. Milder than iodine. d. Carbon chloride CCl4, is a colorless, ethereal fluid which boils at 78° C. Prepared from CHCl₃ by Cl₂ = ClH + CCl₄. When digested with $6KOH = 4ClK + 3OH_2 + CO(OK)_2$. NB. By nascent \mathbf{H}_2 into CHCl₃ or CH2Cl2 or CH3Cl or CH4. [NITRO-METHANE C(NO2)4. TRI-NITRO-METHANE CH(NO₂)₃ is nitro-form.]

By digesting the chloride, bromide or iodide of methyl, with potassium or sodium hydroxide, hydroxyl is substituted for the halogen, and we obtain the first of an homologous series, the Alcohols. The monatomic alcohols are derivatives of the paraftins formed by the substitution of one atom of OH for one

atom of H.

METHANE				C H.	METHYL CHLORIDE	CH, Cl.
ETHANE	•	•	,	C_2H_6 .	ETHYL CHLORIDE	C_2H_5 Cl.
PROPANE				3 0		C_3H_7 Cl.
BUTANE				* 10	BUTYL CHLORIDE,	4 0
PENTANE				C.H.,,	PENTYL CHLORIDE	$C.H_{11}Cl.$

Methyl hydroxide, or methyl alcohol CH₃OH, or HCH₂OH. Woodspirit, or pyroxylic spirit, called Carbinol by Kolbe, the

first term of homologous alcohols, in which monad radicles of the form $C_nH_{2^{n+1}}$ replace one atom of H. Where the monad group in an alcohol of the form $C_nH_{2^{n+1}}$ occurs but once, we have Primary Alcohols; if the replacement occurs twice, we obtain a Secondary Alcohol; but if three units of H in carbinol are replaced by three such groups, we have a Tertiary Alcohol.

CARBINOL CH3.0H or HCH2.0H.

PRIMARY CARBINOL. $\mathbf{CH}_{2}(C_{n}\mathbf{H}_{2^{n}+1}).\mathbf{OH}.$

SECONDARY CARBINOL. **CH** $(C_nH_{2n+1})_2$.OH.

TERTIARY CARBINOL. $C(C_nH_{2n+1}.)_3OH$.

Carbinol, or methyl alcohol, is then a colorless liquid, of penetrating odor, inflammable and volatile. Sp. gr. at o° C. 0.8142. Boils at 65°.5 C. Miscible with water in all proportions, as also with cthyl alcohol and ether. Solvent of resins. Alkalies dissolve and color it brown (URE's test). Burns with paler flame than alcohol. Two stages of oxydation. 1. CH2OH $+ O = OH_2 + FORMYL$ ALDEHYDE CHOH. 2. CH.OH + O =FORMIC ACID CHO.OH. Prep. by destructive distillation of wood, neutralizing with Ca(OH)2, redistilling, rectifying over CaO. Uniting with CALCIUM CHLORIDE : Cl, Ca, 2CH, OH, and decomposing the latter by water. Or from METHYL OXALATE CoO. (OCH,), by distillation with sulphuric acid. Also by saponification of oil of Wintergreen, Gaultheria procumbens with potassium hydroxide. METHYL SALICYLATE C6H4OHCO.OCH3 + KOH = C. H. OH. COOK + METHYL ALCOHOL CH. OH. Artificially by Berthelot. 1. $S_2C + 2SH_2 + 4Cu_2 = 4SCu_2 + CH_4$. $CH_4 + Cl_2 = ClH + CH_3Cl$. And $CH_3Cl + KOH = ClK +$ methyl alcohol CH2OH. "Methylated spirit" is a mixture of 90 per cent. of ethyl alcohol with 10 per cent. of methyl alcohol. Methyl alcohol dissolves Na, which displaces the H of OH, and gives a solid sodium METHYLATE CH, ONa. Distilled with METHYL CHLORIDE OF CHLORO-METHANE CH3Cl, into methylic ether CH30.CH3 + ClNa. With sulphuric acid, methyl alcohol gives methyl-sulphuric acid SO2(OH)(OCH2), in which the H of OH can be replaced by metals. Dimethyl-sulphuric acid SO₂(OCH₃)₂. By distilling, we obtain methyl-ether CH₃.O.CH₃, a pleasant-smelling gas, fluid at - 23° C. N.B. In the formation of an other two molecules of an alcohol part with one molecule of water. Thus: 2CH₂OH = OH₂ + CH₂OCH₂. Methyl-aldehyde HCOH. Colorless gas, obtained by oxydation of vapor of methyl alcohol over red-hot platinum. Reduces Ag2O, and becomes oxydized to FORMIC ACID HCOOH. An aldehyde (alcohol dehydrogenatus) is derived from an alcohol, by elimination of H2 in immediate connection with hydroxyl or of the H2 which belongs to the group CH2OH. The aldehydes are intermediate between alcohols and acids. Thus: HCH2OH + 0 = OH2 + METHYL ALDEHYDE HCOH. A polymeric modification of this gaseous aldehyde exists in a solid state; probably H₃C₃O₃H₃. Formic acid HCO.OH. Colorless liquid, of very acid and piquant odor. Boils at 99° C. and is erystalline at 8°.5 C. It is miscible with water in all proportions, and is an energetic monobasic acid, the first of an homologous series—the fatty acids. It is contained in red ants, in the sting of nettles, wasps, and bees, &c. Prepared by Berthelot: CO + HOK = HCOOK. Most easily by heating at 100° C. equal parts of glycerin and oxalie acid: the latter (CO.OH)₂ = CO₂ + HCOOH. Heated with $SO_2(OH)_2 = OH_2 + CO$. With Ag_2O into $Ag_2 + OH_2 +$ CO. FORMATES. AMMONIUM FORMATE HCO.OH, N, erystallizes in prisms: heated into: 20H2 + HYDROGEN CYANIDE CNH. COPPER FORMATE (CHO)2O2Cu,4OH2, and LEAD FORMATE (CHO), O, Pb, are most characteristic. By distilling HCO.ONa+ HONa = CO(ONa)₂ + H₂. But, by distilling alone: HCOONa + HCOONa = CO(ONa)₂ + HCOH. METHYL FORMATE HCO.OCH3 is a colorless liquid, which boils at 33.04 C. Theoretically, the anhydride of formic acid is obtained from two molecules, by the loss of one molecule of water. Thus: HCOOH + $HCOOH = OH_2 + HCO-O-HCO$. Formamide (HCO)H₂N is a eolorless liquid, boiling at 194°.

Carbonic anhydride CO2. Hypothetical CARBONIC ACID CO(OH)2. In CHLORO-CARBONIC ACID COCl₂, Cl₂ substitutes (OH)₂ in carbonic acid, or one atom of 0 in CO₂. Formed from CO + Cl₂ in

sunlight. Called phosgenc.

Carbonic sulphide SCS = CS2 is the analogue of CO2. P. 12. A colorless liquid of sp. gr. 1.27. Boils at 46° C. $CS_2 + SK_2 = CS(SK)_2$. By nascent H_2 into METHYL-SULPHALDEHYDE **HCSH**: $CS_2 + 2H_2 = S_2II + HCSH$. [Also $CS(SH)_2$. CSSHOH. COSHOH.] METHYL-SULPHYDRATE CH3.SH, is METHYL MERCAPTAN. Colorless, mal-odorous liquid, boiling at 21°C. Prep. by action of HSK upon CH3Cl=ClK+CH3SH. METHYL SULPHIDE CH3SCH3 is the analogue of methyl-ether. It boils at 41°C., and is prepared by using KSK with 2CH3Cl. [Carbonic oxy-sulphide COS colorless gas. Carbonyl sulpho-chloride ClCSCl, by Cl, on CS₂. Thus: SCS + 2Cl₂ = ClSCl + clcScl. Hydrogen cyanide CNH may be regarded as methane in which nitrogen substitutes three atoms of hydrogen; hence azomethane. It may also be called a nitrile, a compound of nitrogen with a trivalent radicle METHENYL. One common method of obtaining a nitrilo is by de-hydrating the ammonium salt of the fatty acid by P_2O_5 . Thus; $HCOOH_4N-2OH_2=CH'''N$ or CNH. And the converso: CNII + 2OH₂ = HCOOH₄N. Cyanogen C₂N₂, or dicyanogen, as it is represented molecularly, is a gas, colorless, of pungent odor resembling prussic acid. Sp. gr. 1.80. Water absorbs four to five vols. Under pressure of four atmospheres into a colorless liquid which boils at - 21° C., and solidifies at - 34° C. Burns with rose-colored flame. Passed into strong ClH, it takes up two of OH, and becomes OXAMIDE C2O2(NH2)2. And, in water, Cyanogen by 40H₂ into AMMONIUM OXALATE (CO.OH₄N)₂. Passed into sol. of HOK iuto CYANIDE and CYANATE: 2HOK + CoNo = CNK + CNOK + OHo. Prep. a. By heating MERCURIC CYANIDE = $Hg + C_2N_2$. A portiou, into brown solid: PARACYANOGEN (C3N3)2, a polymeric modification of C2N2. b. By passing air over a red-hot mixture of potassium carbonate and charcoal: $CO(OK)_2 + 4C + N_2 = 2CN\hat{K} + 3CO$. Cyanides. Cyanogen is a monad radicle. Unites with H. Hydrogen cyanide CNH is commonly called prussic acid. 1782 by Scheele. Anhydrous acid is a colorless, volatile liquid, of sp. gr. 0.7058 at 5° C., boiling at 26°.5 C. Feebly acid. Odor as of peachblossoms. Very poisonous. When inhaled even in small quautities, produces headache, giddiness, &c. Antidotes: chlorine, water, ammonia, affusion of cold water. Cannot be preserved in the light; deposits paracyanogen, evolves ammonia, and ammonium formate always in solution. Used as medicine. Prep. Anhydrous acid. $\dot{\text{CNHgCN}} + \text{SH}_2 = \text{SHg} + 2 \dot{\text{CNH}}$. Of ordinary. a. From bitter almonds, by the action of moist synaptase upon Amygdalin C20H27NO11,3OH2. 17 grains of amygdalin dissolved in 1 oz. of sweet almonds-cuulsion would yield I grain of CNH. The ordinary acid of the Pharmacopeeia contaius 2 per cent. of CNH. Now 100 grains of tartaric acid dissolved in 2 oz. of water, to which 44 grains of CNK have been added, will, when decanted, yield an acid of desired strength. From CNK by dilute SO₂(OH)₂, 2OH₂ = SO₂OH.OK + CNH + 2OH₂. Also from potassium ferrocyanide. Tests: volatility, formation of silver cyunide, of Prussian blue and of ferric sulphocyanide. Potassium Cyanide CNK. In deliquescent, colorless cubes. Alkaline reaction, as in water into hydrocyanide of potash: emits CNH. Soluble in alcohol. Fuses at red-heat. K₂ burns when heated in C₂N₂ into 2CNK. Most easily by heating potassium ferrocyanide with CO(OK). and carbon = 3CO + Fc + 6CNK. Potassium cyanide dissolves iron. In presence of air: 6CNK + Fe + OH, + O = 2HOK $+ C_0 N_6 Fe \hat{K}_4$. In abscuce of air: $6CNK + Fe + 2OH_2 = 2HOK$ $+H_2 + C_6N_6FeK_4$. $-18CNK + 3Cl_2Fe + 2Cl_6Fe_2 = 18ClK +$ C18N18Fe2. Ammonium Cyanide CNH4N, iu colorless cubes: volatile. Very poisonous. By subliming mixt CNK + ClH4N. SILVER CYANIDE CNAg, white, amorphous, soluble in strong NO. OH, H3N and in CNK. Soluble to CNK, CNAg, a double salt. To estimate CNH, add to measured quantity HOK, and then, by a burette, solution of NO2OAg until permanent precipitate appears. As soon as half the quantity of CNH is changed into CNAg, one additional drop precipitates white CNAg, permanent. 170 parts of NO₂OAg correspond to 130 parts of CNK and 54 parts of CNH. Mercuric cyanide C_2N_2Hg in rectangular prisms. 2CNH readily dissolve precipitated HgO = $OH_2 + C_2N_2Hg$. Prep. $C_6N_6FeK_4 + 3SO_4Hg = 2SO_4K_2 + SO_4Fe + 3C_2N_2Hg$. Aurous cyanide CNAu, lemon-yellow powder, not decomposed even by boiling acids. CNK,CNAu much used in electro-gilding. Nickel cyanide C_2N_2Ni , applegreen, readily soluble to $2CNK,C_2N_2Ni$, re-precipitated by ClH. Cobalt cyanide C_2N_2Co is brownish-red, easily soluble in CNK. But, when slightly acidulated and boiled, H_2 is given off and potassium cobalticyanide is obtained, not precipitated by ClH: used to separate Ni from Co. Titanium nitro-cyanide

C2N2Ti,3N3Ti2.

Ferrocyanogen is tetrabasie. Potassium Ferrocyanides. FERROCYANIDE C₆N₆FeK₄. 30H₂. Yellow prussiate of potash. In large lemon-yellow crystals, derived from an octahedron with a square base. Soluble in 4 of eold, and 2 of boiling water. Insoluble in alcohol. Not poisonous; purgative. Source of $\begin{array}{l} {\bf CNH: \ _2C_6N_6FeK_4 + 6(SO_4H_{2,2}OH_2) + aq. = 6SO_2(OH)(OK) + \\ {\bf _{12}OH_2 + aq. + 6CNH + C_6N_6Fe_2K_2, \ known \ as \ EVERITT's \ salt.} \end{array}$ Also of CNK (see above). $C_6N_6FeK_4$ at red-heat = $4CNK + C_2Fe + N_2$. With SO_4H_2 yields CO. Thus: $C_6N_6FeK_4 + C_2Fe + N_3$. Prep. of the salt. From dry animal matters, as horn, hoofs, &e., at a red-heat, in contact with CO(OK)2 and iron-filings. The CNK produced, reacts when water is added upon the iron (see above) and upon terrous sulphide: $6\mathrm{CNK} + \mathrm{SFe} = \mathrm{SK}_2 + \mathrm{C}_6\mathrm{N}_6\mathrm{FeK}_4$. Largely used in making "Prussian blue," and is a delicate test for a ferrie salt: $2\mathrm{Cl}_6\mathrm{Fe}_2 + 3\mathrm{C}_6\mathrm{N}_6\mathrm{FeK}_4 = 12\mathrm{ClK}$ + 2Fe₂, 7FeC₆N₆. With a ferrous salt, a white precipitate C₈N₆Fe₂K₂, turning blue on exposure to air. Thus: C₆N₆FeK₄ + $SO_4Fe = SO_4K_2 + C_6N_6Fe_2K_2$. or Everitt's salt. By air: $6C_6N_6Fe_2K_2 + 3O = Fe_2O_3 + 3C_6N_6FeK_4 + 2Fe_2Cy_6$; $3FeC_2N_2$. Cupric ferrogyanide $C_6N_6FeCu_2$, red-brown: a test for cupric salts. Hydrogen ferrocyanide C₆N₆FeH₄ = CfyH₄. White scales, insoluble in ether. Powerfully acid solution, very soluble in water, and blues on exposure. Ag,, Pb2, Zn2, Mn2 and Bi ferroeyanides are white and insoluble. Ferricyanides. Ferrieyanogen is hexabasic. Potassium ferricyanide $C_{12}N_{12}Fe_2K_6$ is "red prussiate of potash." Ruby-red prisms, freely soluble in water. By passing Cl₂ through sols of 2C₆N₆FeK₄ = 2ClK + C₁₂N₁₂Fe₂K₆. An oxydizing agent in alkaline solutions, thus: $4HOK + 2C_{12}N_{12}Fe_2K_6 = O_2 + 2OH_2 + 4C_6N_6FeK_4$ A test for ferrous: ${}_{3}SO_{4}Fe + C_{12}N_{12}Fe_{2}K_{6} = {}_{3}SO_{4}K_{2} + C_{12}N_{12}Fe_{2}Fe_{3}$ "Turnbull's blue." No precipitate with ferric salts, only browning. Hydrogen ferricyanide C, N, Fe, H, in red, unstable crystals, by decomposing lead ferricyanide by SH, and evaporation. [Nitro-prussides. Sodium nitroprusside C5N5NOFeNa2, ruby-red crystals. By digesting C₅N₅Fe₂Na with NOONa + OH₂ = Fe(OH)₂ + C₅N₅FeNONa₂ Generally by action of nitric acid upon sodium ferrocyanide. Test for alkaline sulphides: gives purple color. Hydrogen nitro-prusside in crystals.] Cobalticyanides. Potassium cobalticyanide (CN), Cook, in vellowish, flattened prisms, isomorphous with C12N12Fe2K6. Chromicyanides. POTASSIUM CHROMICYANIDE (CN) 2 Cr2 Kg, brownish-red prisms. Potassium manganocyanide (CN)₆MnK₁,3OH₂, deep-blue square tables. Potassium man-

GANICYANIDE (CN), MIL, K, deep-red, rhombic prisms.

Cyanogen and Chlorine. CYANOGEN CHLORIDE CNCl, a liquid boiling at 12°, 6 C. By action of Cl, upon CNH. Polymeric modification C₃N₃Cl₃, a solid, by passing Cl₂ into a solution of CNH in ether. CNBr, in needles. CNI, in needles. By action of I_2 upon U_2N_2Hg . Cyanamide CNH_2N from $CNCl+2H_3N$ = ClH_4N+CNH_2N . Methyl cyanide $H_3CCN=(U_2H_3)N$ is ethenyl nitrile. Also called aceto-nitrile, because it can be prepared from acetamide by loss of OH_2 . $C_2H_3OH_2N - OH_2$ = C₂H₃N. By distilling CNK with SO₄CH₃K = SO₄K₂ + H₃CCN. Boils at 77° C. By heating with KOH (absorption of 20H2), into H, N and salt of corresponding fatty acid. As CNH+ $2OH_2 = H_3N + HCOOH_1$, so $H_3CON + 2OH_2 = H_3N + ACETIC$ ACID. CH3COOH. Methyl isocyanide H3CNC, boils at 59° C., of very repulsive odor. From CH3I with CNAg. In isocyanides, C directly united with pentad N. When isocyanide treated with HOK, an amine produced (an alcoholic ammonia) and formic Thus: $H_3\hat{C}NC + 2OH_2 = METHYLAMINE \hat{N}(CH_3)H_2 +$ HCOOH.

Cyanic acid CNOH, limpid, colorless liquid, pungent like acctic acid. By OH2 into H3N and CO2, which unite to CO(OH)(OH4N), and cannot be separated by acids from cyanates. Changes spontaneously into solid CYAMELID (isomeric . Prep. of CNOH: distilling the polymeric modification CYANURIC ACID (CN)3(OH)3 = 3CNOH. Cyanates: by oxydation of cyanides. Potassium CYANATE CNOK, crystallizes from alcohol in thin, transparent plates. Prep. CNK + PbO = Pb + CNOK. Slowly by moisture into H₃N and CO(OH)(OK). Ammonium CVANATE CNOH₄N. By mixing vapor of CNOH with H3N, a white crystalline solid. With ClH, evolves CO2, and with HOK, ammonia. But, if heated, into urea CO(H2N)2 which is metameric with evanate of ammonium. | Cyanuric acid $(CN)_3(OH)_3$, $2OH_2 = C_3N_3O_3H_3$, $2OH_2$, colorless, oblique-rhombie prisms. Tri-basic. Little soluble. Very stable. By passing dry Cl, over melted urea CO H2N/2

and removing H_4NCl by water. $6CO(H_2N)_2 + 3Cl_2 = 2ClH + N_2 + 4H_4NCl + 2C_3N_3O_3H_3$. By heat into eyanic acid. Fulminic acid $C_2N_2O_2H_2$ not known in free state. Dibasic. Silver fulminate $C_2N_2O_2A_2$, white crystalline plates, soluble in 36 of boiling water. Explodes violently when heated or rubbed. $2NO_2OAg + N_2O_3 + C_2H_3OH = 2OH_2 + 2NO_2OH + C_2N_2O_2Ag_2$. Mercuric fulminate $C_2N_2O_2Hg$ resembles the silver salt. In percussion-caps. Fulminaric acid $C_3N_3H_2O_2OH$ is mono-basic.

Also, isocyanuric acid.]

Urea $CON_2H_4 = CO(H_2N)_2$, the most abundant constituent of the urine, was artificially produced by Woehler in 1828 from ammonium cyanate CNOH, N by heating to 100° C. In the urine of man it varies, but may be said to average 1.4 per cent. It crystallizes in long striated needles, very soluble in water and in alcohol. By $2NOOH = CO_2 + 2N_2 + 3OH_2$. By CHLORINE: $CON_2H_4 + OH_2 + 3Cl_2 = 6HCl + CO_2 + N_2$. Heated to 120° C., it fuses and decomposes into Ammeline $C_3N_3OH(H_2N)_2$ and at 150° C. into BIURET C2H5N3O2 [and biuret (3) into 3H3N + 2(CN)3(OH)3. Urea unites with NO2OH, in shiny scales or rhombic prisms to NITRATE CO(H2N)2, NO2OH very little soluble. Obtained by evaporating urine to syrup, and after filtration adding its own bulk of nitric acid. Urea from this nitrate by COO2Ba, evaporation and solution in boiling alcohol, in which barium nitrate insoluble. Oxalate (COOH), 2CON, H, in transparent prisms. Urea from this oxalate by Calcium carbonate and solution in water. With mercuric nitrate urea forms three compounds, and unites also with HgO and other bases. Heated with OH₂ in closed tubes at 100° C., into carbonate of ammonium. It is the Diamide of carbonic anhydride, and contains the elements of ammonium carbonate minus 20H2. Isomeric with CARBAMIDE, but not identical, as when heated with alkaline solution of potassium permanganate it gives off its Nitrogen as such, whereas carbamide has its N oxydized to nitric acid. Artificially prepared from CHLORO-CARBONIC ACID COCI2 + 2H3N = 2ClH + UREA. Also from ETHYL CARBONATE $CO(OC_2H_5)_2 + 2H_3N = 2C_2H_5OH + UREA.$ [Urea containing alcohol radicles. ETHYL-UREA $COH_3(C_2H_5)N_2$. DI-ETHYL UREA COH₂(C₂H₅)₂N₂. METHYL-UREA COH₃(CH₃)N₂, &c., &c.]

Sulphocyanate of potassium CNSK, corresponds to the cyanate CNOK. Deliquescent, striated prisms. Deep-red color with Cl₀Fe₂, bleached by Cl₂Hg, and evolving SH₂ with Zn and acid. Easily prepared by melting CNK with sulphur. Also by calcining S with (CN)₀FeK₄ and CO(OK)₂. CNSNa in the saliva. Hydrogen sulphocyanide CNSH, an oily liquid resembling acetic acid, easily resolving itself into CNH and hydrogen persulphocyanide C₂N₂S(SH)₂. Isosulphocyanide OF Potassium NCSK, from the latter compound by alcoholic HOK.

Browns with Cl_6Fe_2 . By fusion into CNSK. Ammonium sulphocyanate CNS(H_4N) in colorless, deliquescent tables. At 140° C., in part at least into Sulphur-urea $CS(H_2N)_2$, or urea in which S takes the place of O in carbonyl CO.—Allyl iso-sulphocyanate $NCS(C_3H_5)$ pungent, volatile "oil of mustard." By action of myrosin and water upon myronic acid in seeds of black mnstard. Burning taste. Blisters the skin. Boils at 148° C.—By passing Chlorine into CNSK, yellow, insoluble PERSULPHOCYANOGEN $C_3N_3H.S_3$ is produced. Insoluble in water, alcohol and ether. When heated, into hydromellone $C_6N_9H_3$. Thus

 $6C_3N_3HS_3 = 6CS_2 + 3S_2 + 2C_6N_9H_3$.

Amines. Derivates of H₃N by substitution of aleohol-radieles for Hydrogen. Monamines, from one molecule of H₃N by monatomie radieles; Diamines, from two molecules of H₃N by diatomic radieles; Triamines, from three moleenles, by triatomic radieles. The nitrogen may be substituted by Phosphorns, Stibium, Arsenicum. Monamines may be primary, secondary or tertiary, according to removal of one atom, two, or three atoms of hydrogen. The amines resemble ammonia in properties. Thus; tri-methylamine unites with methyl iodide to TETRA-METHYLAMMONIUM IODIDE N(CH₃)₄I. Methylamine NH₂CH₃. Dimethylamine NH(CH₃)₂. Tri-methylamine N(CH₃)₃. Is contained in herring-brine. Tetramethyl-ammonium hydrate N(CH₃)₄OH. When heated into trimethylamine and methylic alcohol: N(CH₃)₃ + CH₃OH.—Tri-methyl phosphine P(CH₃)₃. Colorless oily liquid. With methyl iodide into TETRAMETHYL PHOSPHONIUM IODIDE P(CH₃), I, and this by silver hydrate into TETRAMETHYL PHOSPHONIUM HYDRATE P(CH₃)₄OH.—Tri-methylarsine As(CH₃)₃. Unites with CH₃I to TETRAMETHYL ARSONIUM IODIDE As(CH3)4I, from which AgOH separates the hydrate. Arsen-dimethyl As₂(CH₃)₄ is "cacodyl." Spontaneously inflammable. "Alkarsin." Colorless, transparent liquid, of horrible odor, intensely poisonous. By heating an acetate with arsenious anhydride. Unites with Cl, and splits into two. CACODYL CHLORIDE As(CH₃)₂Cl, colorless, fuming, poisonous liquid; boils above 100° C. With Zn gives pure caeodyl. As(CH3)2I. As(CH₃)₂CN. By slow oxydation caeodyl into Oxide of cacodyl As₂(CH₃)₄O. By further oxydation into Cacodyl dioxide As₂(CH₃)₄O₂. Yet complete oxydation into Cacodylic acid As(CH₃),OOH.—Trimethyl stibine Sb(CH₃)₃. Also: Sb(CH₃)₄I, And Sb(CH₃)₄OH.

Metallic methides. Zinc methyl of zinc methide. Zn (CH₃)₂. By heating methyl iodide with Zine under pressure. Colorless, spontaneously inflammable gas, decomposed by water into zinc-hydroxide Zn(OH)₂ and methane CH₄. Stannous methide Sn(CH₃)₂. Stannic methide Sn(CH₃)₄. Aluminum methide Al₂(CH₃)₆. Mercuric methide Hg(CH₃)₂. Very

poisonous liquid. Lead methide Pb(CH₃)₄. Silicon methide Si(CH₃)4.

II. Di-carbon group C2. Ethane C2H6 and derivatives.

By substituting methyl for hydrogen in methanc, we obtain

dimethyl or ethane. Thus CH3CH3 = C2H6.

Ethane, the second of the paraffin group, C2H6 differs by CH2 from methane, and is the second in this homologous series. $(C_2H_5)_2$ Zn + $2OH_2 = Zn(OH)_2 + 2C_2H_6$. Also by electrolysis of acetic acid: 2CH₃COOH = H₂ + 2CO₂ + CH₃CH₃. Colorless gas, burning with pale flame. By action of chlorine into chlorethane or ethyl chloride C2H3Cl and ClH. Ethene CH2CH2 or C.H., ETHYLENE OF OLEFIANT GAS. Colorless gas, inflammable with bright flame, burning into 2CO + 2OH₂. Dyad radicle. Unites directly with Cl₂, Br₂, I₂. Thus CH₂ClCH₂Cl = C₂H₄Cl₂ is Dutch Liquid. In presence of nascent H2 into ethane again. ETHENE C₂H₄ is prepared by abstraction of OH₂ from ethylic alcohol CoHoOH. It is also called an olefine. Also made by passing the chloride of the alcohol radicle over CaO. Thus: ${}_{2}C_{2}H_{5}Cl + CaO = Cl_{2}Ca + OH_{2} + 2C_{2}H_{4}$. Also from ethine C_2H_2 by H_2 nascent = C_2H_4 . Acetylene or ethine CHCH = C.H., colorless gas of unpleasant odor, burning with sooty flame. Often formed in incomplete combustion of CH4 and of C2H4. Thus: $4CH_4 + 3O_2 = 6OH_2 + 2C_2H_2$. Again: $2C_2H_4 + O_2 =$ 20H₂ + 2C₂H₂. Formed from its elements by heating Carbon points whilst glowing in hydrogen. Also by heating C2H4Br2 with ${}_{2}\mathrm{HOK} = {}_{2}\mathrm{BrK} + {}_{2}\mathrm{OH}_{2} + \mathbf{C}_{2}\mathbf{H}_{2}$. Ethine by nascent hydrogen into ethene. It is absorbed by ammoniacal cuprous

chloride and silver nitrate: $C_4Cu_4OH_2$. $C_2Ag_2OH_2$.

Ethyl hydroxide or Methyl carbinol. $C_2H_5OH = C\{CH_3H_2OH = CH_3CH_2OH$. As "absolute alcohol," colorless, volatile, of strong spirituous odor. Inflammable; burning to ${}_2CO_2$ and 3H₂O. Sp. gr. 0.8095 at 0° C., and 0.794 at 15°.5 C. Never frozen. Viscid at -110° C. Boils at 78°.5 C. Great affinity for water. A solvent of gases, deliquescent salts, but not of CO(OK), of HOK, HONa, of I (tiucture), Br, of resins (varnishes), essential oils (various Eaux de) alkaloids, &c. Fats and fixed oils, except castor-oil, but little soluble. alcoates: in them it takes the place of water of crystallization as in Cl₂Ca,4C₂H₅OH. "Proof-spirit" contains 49.24 per cent. of alcohol by weight. Practically every additional 0.5 per cent. of absolute alcohol, to proof-spirit, is one degree above proof. Absolute alcohol is made by long digestion of rectified spirit of wine upon CaO, and distillation. Can be made from its elements: a. From $C_2 + H_2$ at white-heat $= C_2H_2$. b. Ethine C₂H₂ by nascent H₂, into ethene C₂H₄. c. Ethene C₂H₄ with SO₂(OH), into ethyl sulphuric acid SO₂OH(OC₂H₅). d. By 2HOK into SO₂(OK)₂ + OH₂ + CH₃, CH₂OH. Or by distillation with water, into sulphuric acid and ethyl alcohol. VINOUS FERMENTATION. The ferment is probably a fungus Torvula cerevisiae and Penicillium glaucum, which lives upon the albumen contained in juice, say of grape, and induces a change which brings about the alcoholic fermentation of the GLUCOSE C₆H₁₂O₆ into 2CO₂ + 2CH₃.CH₂OH. Temperature of 21°.2 C. most favorable to termentation. Port contains from 15 to 17 per cent, of alcohol calculated as absolute; Sherry, 14 to 16 per eent.; Madeira, 14 to 17; Amoutillado, 12.6; Clarct. 8 to 9; Rhine wines from 7 to 10 per cent. Claret, Burgundy, and Rhine wines contain but little sugar; sherry less than port. CREAM OF TARTAR C2H2(OH)2(COOH)(COOK) in all grapevines: least in old wines. Alcohol, as genuine wine, rouses sluggish digestions, limits the metamorphosis of food, gives temporary strength to nervous system, earries off the effects of chills, and prevents the absorption of bad odors. When diet is insufficient, it arrests the progress of decay till nature can again assert the power of the stomach to take food.

Ethers of ethylic. Chlorethane C₂H₅Cl = CH₂CH₂Cl. Colorless, volatile liquid, of sp. gr. 0.921, boils at 12°. 5°C. By Cl. in excess, into C₂Cl₆ ultimately. With aqueous HOK = ClK + C₂H₅OH. With alcoholic HOK into ClK + C₂H₅OC₂H₅. Also with $C_0H_5OK + C_0H_5Ol = ClK + C_2H_5OC_2H_5$. With soda-lime into 2ClNa + OH₂ + C₂H₄. Prep. from ClH upon C₂H₅OH = OH, + C, H, Cl. Bromethane C, H, Br. Volatile liquid, heavier than water. HODETHANE College or ETHYL IODIDE. Colorless liquid, of ethereal odor, of sp. gr. 1.92 and boils at 72° C. Very important. By distilling 70 parts of alcohol, 100 parts of iodine and 5 parts of phosphorus. Praetically PI₃ + 3C₂H₅OH = P(OH)₃ +3CoHs1. CYANETHANE OF ETHYL CYANIDE CNC. Hs, is PROPENYL NITRILE C₃H₅N. Boils at 82° C. By heating with KOH + 20H₂ = H₂N + PROPIONIC ACID C₂H₅COOH. ETHYL ISO-CYANIDE NCC_2H_5 by $2OH_2 = ETHYLAMINE (C_2H_5)'H_2N + FORMIC ACID$ HCOOH. ETHYL OXIDE OF ETHYL ETHER C.H.OC.H. = C.H.O is common "ether." Colorless, transparent, tragrant liquid, very mobile. Sp. gr. 0.72. Boils at 35°.6 C. Very combustible: one molecule of the vapor requires six molecules of O. Miscible with alcohol in all proportions. Ten parts of water take up one part of ether. Solvent of oils and fats, and of some salts and alkaloids. Vapor very heavy; 2.586 that of air. By long action of Cl₂ in sunshine into C₄Cl₁₀O.

When Na introduced into cthyl alcohol, sodium ethylate C_2H_5ONa is produced and H. Potassum ethylate C_2H_5OK , by same means. Thus: $2C_2H_5OH + K_2 = 2C_2H_5OK + H_2$. Now: $C_2H_5OK + C_2H_5OK + C_2H_5$

acid.) ETHYL SULPRIDE C2H5SC2H5, colorless oily liquid, of pungent alliaceous odor, of sp. gr. 0.825, and boils at 72° C. Very inflammable. ETHYL HYDROGEN SULPHIDE C2H5SH. MER-CAPTAN. Colorless, limpid fluid of sp. gr. 0.842. Boils at 36° C. (See methyl, p. 85.) ETHYL NITRATE NO₂0C₂H₅. Sp. gr. 1.112. Insoluble in water. Boils at 85° C. Urca employed to prevent the formation of nitrite. (See UREA, p. 89.) ETHYL NITRITE NOOC2H3. Pale-yellow liquid, with odor of apples. Sp. gr. 0.947: boils at 16°.6 C. A solution in alcohol mixed with aldehyde, constitutes Spiritus etheris nitrosi. Ethyl formate HCOOC, H3. Liquid of faint odor as of CNH. Sp. gr. 0.915. Boils at 53° C. ETHYL SULPHATE SO, (OC, H,)2. Syrup which cannot be distilled. ETHYL HYDROGEN SULPHATE or sulphovinic acid S020H0C2H5. Sour, syrupy liquid, in which sulphuric acid not recognizable by ordinary tests. By mixing rectified spirit with twice its weight of sulphuric acid. CALCIUM ETHYL-SUL-PHATE. SO₂(OC₂H₅)₂,SO₂(O₂Ca),2OH₂ colorless, transparent crystals. Distilled with HSK, gives mercaptan. Potassium ethyl SULPHATE SO₂(OC₂H₅)(OK) by CO(OK)₂ from former salt. When a thin stream of C2H50H is poured into boiling Ethyl hydrogen sulphate, at a temperature of about 149° C., continuous etherification is effected. Thus: SO₂(OH)(OC₂H₅) + C₂H₅OH = $SO_2(OH)_2 + C_2H_5OC_2H_5$. Then: $SO_2(OH)_2 + C_2H_5OH =$ $OH_2 + SO_2(OH)(OC_2H_3)$. ETHYL-DIHYDROXYL PHOSPHATE PO(OH)2OC2H3. ETHYL BORATE BO(OC2H3). ETHYL SILICATE $Si(OC_2H_5)_1$. From $Cl_4Si + 4C_2H_5OH = 4ClH + Si(OC_2H_5)_4$. ETHYL CARBONATE CO(OC2H5)2. Aromatic liquid; boils at 125° C. $CO(OAg)_2 + 2C_2H_5I = 2IAg + CO(OC_2H_5)_2$. ETHYL HYDR-OXYL CARBONATE CO(OH)(OC2H5). Crystalline. By passing dry CO, into solution of HOK in absolute alcohol. ETHYL SULPHO-CARBONATES. $CO(0H)SC_2H_5$. $CO_2S(C_2H_5)_2$.

Double ethers. METHYL-ETHYL ETHER CH3OC2H5. Boils at

11° C. Thus: $CH_3OK + C_2H_5I = IK + CH_3(OC_2H_5)$.

Ethyl aldehyde $H_3C(COH) = C_2H_4O$. Colorless, mobile, ethereal liquid. Sp. gr. o.8. Boils at 21° C. Inflammable. Reducing agent. Thus: $Ag_2O + H_3C(COH) = H_3C(COOH) + Ag_2$. With alkaline acid sulphites, crystalline compounds, as $80(0H)(0Na).C_2H_1O$. By nascent H_2 , into respective alcohols. H_3N in ethereal solution of aldehyde, gives crystalline ALDEHYDE-AMMONIA $H_3CCHOHII_2N = C_2H_4(H_3N)O$. Heated with $H_3CHOHII_2N = C_2H_4(H_3N)O$. By $CI_5P = POCI_3 + chloraldehyde CII_3.CHCI_2$. By $CI_2 = CIH + acetyl chloride <math>C_2H_3O$.CI. Fused with $HOK = H_2 + C_2H_3O(OK)$. Several polymeric modifications, as paraldehyde, and metaldehyde, ALDOL is another. Prep. distilling $C_2H_3(OH)$ with $SO_2(OH)_2$ and $CrO_3,CrO_2(OK)_2$: O_2 oxydizes two mols. of alcohol by removing $2OH_2$. Also, by distilling sodium acetate

with sodium formate: into $CO(ONa)_2 + H_3CCOH$. Acetal $C_2H_4O.O(C_2H_5)_2 = C_6H_{14}O_2$, is aldehyde-ether. Colorless, ethereal liquid of sp. gr. 0.821 at 22°.2 C., and boils at 140° C. By platinnm black into aldehyde, and then, acetic acid. From $C_2H_4O.C_2H_5Cl$ by $C_2H_5ONa = ClNa + Acetal$. Chloral or Chloraldehyde $CCl_3COH = C_2HCl_3O$. Thin, oily, colorless fluid, of penetrating odor. Sp. gr. 1.502. Boils at 94° C. Freely soluble in water, alcohol, and ether. With a small quantity of water, it forms Chloralhydrate C_2HCl_3O,OH_2 . Much nsed in mcdicine. Unites also with cthylalcohol. Heated with alkalies into Chloroform $CHCl_3$ (p. 83) and formate of the metal. Behaves like an aldehyde. By O into Tri-chloracetic Acid CCl_3 , COOH. Prep. by action of $4Cl_2$ upon ethyl-alcohol, or of $3Cl_2$ upon aldehyde. Thus: $CH_3CH_2OH + 4Cl_2 = 5ClH + 4Cl_3 = 5ClH$

CCl₃,COH. Bromal CBr₃,COH. Boils at 172° C.

Acetic acid $H_2C.COOH = CH_2COOH$ or $C_2H_1O_2$. The second of the fatty acids, derived from the paraffin series of hydrocarbons. Monobasic. Is found in the juices of many plants as acetate. Glacial acetie acid, in Instrous plates, fusing at 17° C. Sp. gr. of liquid 1.055. Boils at 118° C. Miscible with water, alcohol and ether. Five per eent, or less in vinegar. "Pyroligneous acid" by destructive distillation of wood. prepared by oxydation of alcohol. H₂CCH₂OH + O₂ = OH₂ + H.CCOOH. Phosphoric chloride changes acetic acid into Acetyl chloride C_2H_3OCl . Thus: $C_2H_3O.OH + PCl_5 = POCl_3 + ClH$ + C₂H₃OCl. By passing the vapor of acetic acid through a redhot tube, we obtain Acetone CH3COCH3. Acetates. Potassium acetate CoH3O.OK, foliated, deliquescent. Used in medicine as a diuretic. Sodium acetate CoH3O.ONa,3OH, in oblique rhombic prisms, very soluble in water. Used in making the acid with SO₄H₂, Also for METHANE CH₄. Thus: CH₃COONa + HONa = CO(ONa)₂ + CH₄. Ammonium acetate CH₃COOH₄N, diaphoretic. Important. Heated with P₂O₅, loses 2OH₂, into Ethenyl nitrile (C2H3)N or aceto-nitrile. Methyl acetate CH₂COO(CH₂), in wood spirit. Colorless, fragrant liquid. Boils at 55° C. Ethyl acetate CH3CO(OC2H5), fragrant limpid fluid, of sp. gr. o. 89, and boils at 73°.8 C. By distilling sodinm acetate with ethyl alcohol and sulphurie acid. Thus: CH3CH2OH + $SO_4H_2 + CH_3CO(ONa) = SO_2(OH)(ONa) + CH_3CO(OC_2H_2).$ Acetamide CoH2O, H2N, white crystalline solid, melting at 78° C. From ethyl acetate and H₃N. Also from ammonium acetate -OH₂. Also from C₂H₃OCl + H₃N = HCl + Acetamide. Behaves like an acid and a base. By loss of OH, into ACETO-NITRILE (C.H.)N. Heated with ClH into ClH, N + Diacetamide (C2H3O)2HN: it is a secondary monamine, just as acetamide is a primary. Ethyl-acetamide (C2H3)(C2H3O)HN is formed from ethylamine and acetyl chloride with loss of ClH. Lead acetate

(C₂H₃OO),Pb,3OH₂ is sugar of lead, in right-rhombic prisms, or in masses of white crystals. Soluble in less than 2 of water. By heat, anhydrous; then fuses. If temperature raised, into PbO, CO2, and Acetone C2H3O, CH3 or acetyl methyl. But acetone is better prepared by distilling CALCIUM ACETATE (CH₃)₂(COO)₂Ca = CO(O₂Ca) + Acetone. Colorless liquid. Boils at 56° C. Behaves like an aldehyde, but with nascent H2 yields SECONDARY PROPYL ALCOHOL CH3. CHOH. CH3 (p. 101). Acetone also, from zine methide and acetyl chloride: (CH2)2Zn + 2CH3.COCl = Cl2Zn + 2CH3.CO.CH3. Goulard extract is BASIC ACETATE 2PbO, (C2H3O)2O2Pb,OH2. In crystals, by addition of H3N to acetate of lead. Formed in manufacture of white lead Ph(OH)2,2COO2Pb. Copper acetate (C2H3O2)2Cu,OH, in green crystals, soluble in 14 of water. Verdigris is basic acetate. Silver acetate C.H. O(OAg). small colorless needles, little soluble in water. Mercurous acetate, small scales, very little soluble. Ferric acetate, dark red-brown, uncrystallizable. Ag, Hg2, and Fe, salts, are tests. Acetic oxide is the Anhydride (C2H3O)2O = (C₂H₃O)O(C₂H₃O). Heavy oily liquid, slowly by water into acetie acid. Prep. From acetyl chloride on sodium acetate = $ClNa + (C_2H_30)_90.$

Chloracetic acids. By action of Cl2 upon acetic acid in sunshipe. The Cl substitutes one, two, or three atoms of Hydrogen in acetyl C2H3O. Mono-chloracetic acid (CH2C1)COOH. DI-CHLORACETIC ACID (CHCl2)COOH. TRI-CHLORACETIC ACID (CCl₂)COOH. With H₃N yields Chloroform (p. 83). Bromacetic acids. Iodacetic acids. Thiacetic acid CH3COSH, by P2S5 on $_5$ CH₃COOH = $P_2O_5 + _5$ CH₃COSH. Amidacet c acid UH₂(H₂N) COOH is Glycocin, or gelatin-sugar. Transparent crystals easily soluble in water. Prepared by 2H3N upon monochloracetic acid = ClH4N + glycocin. See hippuric acid, p. 114. Nitrous acid changes it into OXY-ACETIC OF GLYCOLLIC ACID CH2OH.COOH+N2+OH2. Methyl glycocin or Sarcosin CH2 (CH3.HN)COOH, colorless, rhombic prisms, isomeric with alanin. By boiling creatin with Baryta water; also by digesting ethyl chloracetate with aqueous solution of methylamin. Thus: $CH_2CI.COOC_2H_5+CH_3.H_2N+OH_2=CIH+C_2H_5OII+methyl$ glycocin CH, HNCH, COOH. It combines with acids to form salts. When heated with soda-lime it gives off methylamin (p. 90).

Amines.—Ethylamine $C_2H_3H_2N = C_2H_7N$. A primary amine, or ammonia in which the alcohol radicle "ethyl" replaces H atom for atom. On digesting bromethane C_2H_3 Br with alcoholic solution of H_3N , ethyl-ammonium bromide $C_2H_5H_3N$ Br is obtained; on distilling with C_4OOH_2 , C_4C_4 and C_4C_4 result. Or, from ethyl-isogyanate C_4C_4 by 2HOK = C_4C_4 NH₂C₂H₃. Mobile liquid of sp. gr. 0.696. Boils at 19°C. Odor of ammonia. White clouds with CHI. Crystallizable

salts. Vapor inflammable. Decomposed by $2NO(OH) = N_2 + 2OH_2 + NO(OC_2H_5)$. The nitrites of alcoholic radicles thus produced, easily resolved into corresponding alcohols by distillation with KOH. The iso-cyanides easily prepared from the alcohols, and by nascent H_2 they are changed into Amines. Thus we pass from a lower to a higher alcohol. By passing vapor of CN(OH) into $(C_2H_5)H_2N$, we obtain ETHYL-UREA $COH_3(C_2H_5)N_2$. Diethylamine $(C_2H_5)_2HN$, by mixing ethylamine with ethyl iodide, &c. Triethylamine $(C_2H_5)_3N$. Tetrethyl-ammonium hydrate $(C_2H_5)_4N$.OH. From iodide by HOAg. Analogous to KOH. By heat $= (C_2H_5)_3N + OH_2 + C_2H_4$. Triethylphosphine $(C_2H_5)_3P$. Triethylstibine $(C_2H_5)_3$ Sb. By distilling $_3(C_2H_5)$ with an alloy of SbK_3 , &c. Triethylarsine $(C_2H_5)_3A$ s, &c.

ethylbismuthine (CoH5)3Bi.

[A dicarbon monatomic alcohol not belonging to the primary alcohols of the paraffin series is, vinyl alcohol C.H. Prepared by Berthelot from ETHINE C2H2, by combining with SO₂(OH), to VINYL-SULPHURIC ACID SO₂(OH)(OC₂H₃), and distilling with water. The radical vinyl is univalent. Only two alcohols of this series are known. 1. VINYL ALCOHOL. 2. ALLYL ALCOHOL C₃H₅OH, see p. 102.] Ethene or ethylene C₂H₄, p. 91, is a dyad radical. It is the basis of a series of diatomic alcohols, derived from the paraffins by substitution of OH for H. Thus: C₂H₆ becomes C₂H₄(OH)₂. 1. Methene CH₂ is unknown. Its oxygen compound is CO. [Its glycol, METHENE GLYCOL (CH₂)"(OH)₂, cannot attract to itself more than one atom of METHINE ACETATE (CH2)"(OC2H3O)2. Oily liquid. From METHENE IODIDE CH2I2 on C2H3O(OAg). METHENE OXIDE (CH₂)"O or rather (CH₂)₃O₃.] 2. Ethene alcohol is Glycol CoH, (OH). Colorless inodorous liquid of sp gr. 1.125. Boils at 197°.5 C. Miscible with water in all proportions. Prepared from ETHENE BROMIDE C. H. Br., by silver acetate 2(CH3COOAg)

 $= 2 \text{BrAg} + (\text{C}_2 \text{H}_3 \text{O}.\text{O})_2 \text{C}_2 \text{H}_4$. By distilling acetate of ethene with $Ba(OH)_2 = (C_2H_3OO)_2Ba + C_2H_4(OH)_2$. Potassium may expel one or two atoms of H in OH, and yield monor di-etherate. Ethers of the glyeols obtained by treatment with iodmethane, iodethane, &c. Thus: C₂H₄(OH)(ONa) + $C_0H_4I = INa + ETHYL ETHENATE C_2H_4(OH)(OC_2H_5)$. Again: C2H4(ONa)2 + 2C2H5I = 2INa = DIETHYL ETHENATE C.H4 (OC.H.). Hydroxyl-acids produce ethereal salts, but the hydracids of Cl. Br, I, &c., only remove one atom of OH, forming ETHENE CHLORHYDRATE C2H4OH.Cl. DICHLORINATED ETHER C2H4Cl2 can only be produced from the alcohol by 2Cl5P = 2CIH + 2POCl₃ + ETHENE DICHLORIDE C₂H₄Cl₂, the Dutch liquid of Chemistry. C, H, Cl, is a thin eolorless liquid, of ethereal odor; heavier than water. Boils at 82°. 3 C. Prepared by mixing Cl₂ with C₂H₄. C₂Cl₆ is a white erystalline, aromatic substance, the analogue of ETHANE C2H6'. C2Cl2 in white needles, obtained by passing CHCl, or CoCl, through a red-hot tube. ETHENE BROMIDE (C2H4)"Br2, boils at 129°.5 C. ETHENE IODIDE C2H4I2, a crystalline substance, made by acting upon C₂H₄Cl₂ with I₂. Ethene cyanide (C₂H₄)"Cy₂, erystalline, melts at 50° C. By distilling 2CNK + C₂H₄Br₂ = 2BrK + $C_{v_2}(C_2H_4)''$. Ethene oxide $(C_2H_4)''O$, transparent, eolorless fluid; boils at 13°.5 C It takes up naseent H, and becomes ethyl-aleohol. From ETHENE CHLOR-HYDRIN C2H4OHCl + HOK = $ClK + OH_2 + ETHENE$ OXIDE C_2H_4O . It is a powerful base, and unites with H₃N to form basic compounds with 1, 2, 3 and 4 molecules of C2H4, of syrnpy character and no crystalline eompounds with acid sulphites. Ethene oxide is thus distinguished from aldehyde or ETHIDINE OXIDE CH3COH. ETHENE SULPH-HYDRATE C2H4(SH)2, colorless oil, insoluble in water. From C, H, Br, by 2SHK. ETHENE SUIPHIDE (C, H,)"S,(C, H,)"S. Crystalline solid. Vapor-density 60. ETHENE SULPHONIC ACID C₂H₁(SO₃H)₂, difficult to erystallize. By oxydation of the sulph-hydrate of ethene, or by boiling ethyl-aleohol with sulphurie anhydride. C2H4(OH)SO3H is isethionic acid, and isomeric with ethyl sulphuric acid $C_2H_5HSO_4$. Unerystallizable liquid, decomposed by boiling with water. Ammonium isethionate C₂H₄OHSO₃H₄N, heated to 230° C., into OH₂ and etheneamido-sulphonic acid or Taurine C2H4(H2N)SO3H. Isethionic acid, by oxydation of the sulph-hydrate of etheno, or by action of nitrous acid on taurine = N2 + OH2 + isethionic acid (C₂H₁)"(OH)SO₃H.

Taurine $C_2H_4(H_2N)SO_3H$ is found in the bile of oxen, &c, in combination with cholic acid, and is prepared by boiling Taurocholic acid $C_{26}H_{45}NSO_7 + OH_2$ with HOK. In rhombic

prisms, easily soluble.

ETHIONIC ANHYDRIDE $C_2H_4(SO_3)_2$, in deliquescont needles.

By OII, into Ethionic acid CoH4(OSOOH)SOOH. Resolved by boiling water into SO₀(OH), + isethionic acid C₂II, (OH)(SO₃H). Glycol (CH,OH), or C,H,(OH), by oxydation, forms the first of a series of diatomic and monobasic acids. Glycollic acid C2H4O3 = CH₂"(OH)(COOH) or OXY-ACETIC ACID, is the first of the lactic series, or oxy-fatty acids. Sometimes syrupy liquid, at others crystalline. Sour, very soluble, begins to boil at 100° C. (By dehydrants, from 2 mols, minus OH, into dibasic DI-GLY-COLLIC ACID C₄H₆O₅.) Prep. from Glycol by platinum-black. From glycoein, p 95, by nitrous acid. From bromacetic acid by HOAg. CH, Br(COOH) + HOAg = BrAg + CH, OHCOOH. From OXALIC ACID by 2H2. By further oxydation of a glycol, we obtain a series of diatomic, dibasic acids. They all contain 4 atoms of O. 1. Oxalic acid $C_2H_2O_4$, $2OH_2 = (C_2O_2)''(OH)_2 2OH_2$. Oblique, rhombie prisms, soluble in 8 of water, and in their own weight of boiling water. Poisonous: magnesia or chalk the best antidotes. Reduces Cl₃Au. Thus: 2Cl₃Au $+ 3[(C_2O_2)''(OH)_2] = 6ClH + 6CO_2 + 2Au$. By SO_4H_2 into SO_4H_2 , $OH_2 + CO_2 + CO$. All oxalates decomposed by heat, generally into carbonate, and Carbonic oxide, sometimes into metal and CO_2 , without blackening. $(C_2O_2)''(OK)_2, {}^2OH_2$ in rhombie prisms. $(C_2O_2)''OH, OK, {}^2OH_2$, is salt of sorrel. In Rumer, Oxalis acetosella, &c. Soluble in 40 of water, and 6 of boiling. QUADROXALATE (C2O2)"OH,OK,(C2O2)"(OH)2. SODIUM OXALATE VERY little soluble. AMMONIUM OXALATE $(C_2O_2)''(OH_4N)_2, 2OH_2$: by heat into $2OH_2 + oxampe (C_2O_2)''$ (HoN)2. Heated with a de-hydraut into 40H2+di-cyanogen C2N2. Cyauogen in water $+(40\dot{H}_2) = (C_2O_2)''(0\dot{H}_4N)_2$. Ammonitm HYDROXALATE $(C_2O_2)''(OH)(OH_4N),OH_2$. By heat at 232° C., into oxamic acid $(C_2O_2)''(OH)(H_2N)$. Calcium oxalate (C2O2)"O2Ca,4aq. white, insoluble in water and in acetic acid. "Mulberry ealculus," because often blood-stained. By heat = $CaO_1CO_2 + CO_2$. Lime and soluble salts, a test. $(C_2O_2)O_2$ Fe nearly insoluble. Ferric soluble. (C2O2)"(OC2H5)2 is oxalic ether. Colorless, oily liquid of aromatic odor, and 1.09 sp. gr. Boils at 183°.8 C., little soluble in water. With 2H3N into ethyl-aleohol and oxamide (C2O2)"(H2N)2. With dry gaseous ammonia, ethyl oxalate yields alcohol, and ETHYL OXAMATE $(C_2O_2)''(H_2N)(OC_2H_5)$. Oxamide $(C_2O_2)''(H_2N)_2$ a white powder, insoluble in water and in alcohol. Its vapor through red-hot tube : $2(C_2O_2)''(H_2N)_2 = CO''(H_2N)_2 + CNH + H_3N + CO +$ CO2. It is formed when 2CNH + O2H2 are brought together. By dilute acids into oxalic acid and an ammonium salt. Di-METHYL OXAMIDE $(C_2O_2)''(CH_3)_2NH_2N.$, &e. ETHYL CARBONATE (CO)"(OC2H5)2 by K or Na upon ethyl oxalate: CO evolved. METHYL OXALATE (C2O2)"(OCH3)2, in transparent rhombs. Melts at 53° C. Boils at 161° C. With dry H2N into methyl

oxamate $(C_2O_2)''(H_2N)OCH_3$. ETHENE OXALATE $(C_2O_2)''(OCH_2)_2$ from silver oxalate by $C_2H_4Br_2$. Prep. of oxalic acid. 1. From calcium oxalate by $SO_2''(OH)_2$. 2. from sugar by oxydation with nitric acid: $C_{12}H_{22}O_{11} + 9O_2 = 5OH_2 + 6$ oxalic acid. 3. by heating potassium-amalgam in CO_2 ; or Na_2 in $2CO_2 = (C_2O_2)''(ONa)_2$. 4. Upon a large scale, by heating sawdust with mixt KOH + 2NaOH at about 204° C. and treatment with water, which leaves sodium oxalate undissolved. From $(C_2O_2)''(ONa)_2 + Ca(OH)_2 = (C_2O_2)''(O_2Ca) + 2NaOH$. From calcium oxalate by sulphuric acid: $(C_2O_2)''O_2Ca + SO_2(OH)_2 = SO_2O_2Ca + (C_2O_2)''(OH)_2$.—2. Malonic acid $C_2H_4O_4 = (C_3H_2O_2)''$ $(OH)_2 = (CH_2)''(COOH)_2$; rhomboids. Melts at 140° C. At 150° C. into $CO_2 + (CH_3)COOH$. By oxydizing malic acid $CO_2 + CO_2 + CO$

Mesoxalic acid $CO(COOH)_2 = C_3H_2O_5$ by substitution of O for H_2 in Malonic acid $CH_2(COOH)_2$. Deliquescent prisms, containing OH_2 . Melts at 115° C. By oxydizing amidomalonic acid $CH(NO)(COOH)_2 + O = H_3N + CO(COOH)_2$. Also from alloxan + 2OH₂ (boiled with alkalies) = $CO(H_2N)_2 + CO(COOH)_2$. Nascent H_2 converts mesoxalic acid into Tar-

TRONIC ACID CH(OH)(COOH),

3. Succinic acid $(C_2H_4)''(COOH)_2 = C_4H_6O_4 = (C_4H_4O_2)''(OH)_2$. Colorless oblique rhombic prisms, soluble in 5 of cold and 3 of boiling water. Melts at 180° C.; boils at 235° C., loses OH2 and becomes SUCCINIC OXIDE OF ANHYDRIDE (C,H,O2)"O. Also: $C_2H_4(COOH)_2 + Cl_5P = Cl_3OP + 2ClH + (C_4H_4O_2)"O$. Alkaline succinates readily soluble. Ferric succinate, red-brown precipitate, dissolved by ClH. Succinates, not precipitated from salts by acids, but, in the cold, by ClaBa, after addition of H₃N and alcohol. Succinic acid exists ready formed in amber (succinum). Most easily obtained by fermenting calcium malate. (See Malic acid C₂H₃(OH)(COOH)₂, p. 105.) Also by oxydizing BUTYRIC ACID C₃H₇(COOH) = OH₂ + succinic acid. Also by action of IH upon malic acid. Thus: C2H3OH(COOH)2 + 21H = I₂ + OH₂ + succinic acid.—Also from ETHENE CYANIDE $(C_2H_4)''C_2N_2$ by alcoholic potassoxide. Thus: $(C_2H_4)''C_2N_2 +$ $2 \text{HOK} + 2 \text{OH}_2 = 2 \text{H}_3 \text{N} + \text{POTASSIUM SUCCINATE.} (\text{C}_2 \text{H}_4)'' (\text{COOK})_2$ Also by nascent H₂ to Funanc acid (C₂H₂)"(COOH)₂. Monobromsuccinic acid C₂H₃Br(COOH)₂ by heating the acid with Br, and water in sealed tubes to 160° C. In groups of needles, easily soluble. Melts at 160° C., evolves BrH, and becomes fumaric acid. By boiling with HOAg, into BrAg and malic acid $C_2H_3OH(COOH)_2$. Di-bromsuceinic acid $C_2H_2Br_2(COOH)_2$ in prisms. By 2HOAg into inactive tartaric acid $C_2H_2(OH)_2$ (COOH) $_2$. [Succinyl chloride $(C_2H_4)''(COCl)_2$. Oily liquid, produced by action of PCl_5 upon suceinic acid.] [Belonging to the same group, as 1. Oxalic acid $(C_2O_2)''(OH)_2$, p. 98; 2. Malonic acid $(CH_2)(COOH)_2$, p. 99; 3. Succinic acid $(C_2H_4)''(COOH)_2$, p. 99; we have to mention: 4. pyro-tartaric acid $(C_3H_6)''(COOH)_2$. 5. Adipic acid $(C_4H_8)''(COOH)_2$. 6. Pimelic acid $(C_5H_{10})''(COOH)_2$. 7. Subcric acid $(C_6H_{12})''(COOH)_2$, white crystalline powder. 8. Anchoic acid $(C_7H_4)''(COOH)_2$. 9. Sebasic acid $(C_8H_{16})''(COOH)_2$. In pearly scales; melts at 127° C. 10. Brassylic acid $(C_9H_{18})''(COOH)_2$. 11. Roccellic acid $(C_{15}H_{30})''(COOH)_2$.]

III. Tricarbon C3 or Propane group C3H6.

All compounds which contain three carbon atoms linked together are derived from the paraffin propane C₃H₈ = CH₃-

CH₂-CH₃.

Propane $C_3H_8=CH_3-CH_2-CH_3$, is a gas, liquefying at -20° C. Methyl-ethyl. By action of zinc and 2ClH on (2) Propyl 10D1DE C_3H_7I . Also contained in petroleum. Exposed to Chlorine in sunlight, partly into Propyl Chloride C_3H_7CI . Colorless liquid. Boils at 47° C. Also from normal propyl alcohol by ClH. Pseudopropyl Chloride CH_3 -CHCl-CH3, boils at 37° C. Propyl 10D1DE CH_3 -CH2-CH2-CH2-CH3, an oily liquid of sp. gr. 1.7. Bromine expels iodine. Best prepared by action of hydrogen 10D1DE IH upon Glycerin; $C_3H_5(OH)_3 + 5IH = 2I_2 + 3OH_2 + C_3H_7I$. By nascent $H_2 = IH + C_3H_8$ or normal propyle: C_3H_7CI or CH_3 -CH2-CH2Cl, and this, heated with potassium acetate, yields normal propyl alcohol CH_3 -CH2-CH2-OH. A generic method of obtaining the normal from the abnormal.

Primary propyl alcohol $C_3H_7OH = CH_3-CH_2-CH_2OH$. In this, as in other primary alcohols, hydroxyl is attached to a earbon-atom at the end of the chain. Also: Ethyl-carbinol. Boils at 96° C. Freely soluble in water. In the residues of certain French brandies. From propionic allehydd CH_3-COH_2-COH by nascent $H_2 = CH_3-CH_2-CH_2OH$. Also from emulyl cyanide $CH_3-CH_2-COH_2$ into propylamine $CH_3-CH_2-CH_2$, it is by 2NO(OH) into $2OH_2 + N_2 + PROPYL$ nitrite. Then: $NO(OC_3H_1) + HOK = NO(OK) + C_3H_7OH$.—Propylic aldehyde CH_3-COH_2-COH or C_3H_6O , of sp. gr. 0.804. Boils at 49° C. Resembles acetic aldehyde. Obtained by oxydizing the normal alcohol, or by distilling a mixture of ealcium

formate and propionate: (CH₃-CH₂COO)₂Ca + (H-COO)₂Ca = ${}_{2}\text{COO}_{2}\text{Ca}$ + propylic aldehyde (2 mols.).—Propionic acid $\text{C}_{2}\text{H}_{3}\text{COOH} = \text{C}_{3}\text{H}_{6}\text{O}_{2}$. Is the third of the series of the fatty acids, of which FORMIC ACID H.COOH, is the first, and ACETIC ACID CH3-COOH, is the second. Colorless liquid, of sp. gr. 0.992. Soluble in water; the Propionates also. Prep. From ETHYL CYANIDE C2H3CN + HOK + OH2 = H3N + POTASSIUM PROPIONATE, and from this by distillation with PO(OH)3. Also from Lactic acid $C_3H_6O_3 + 2IH = I_2 + OH_2 + C_2H_3$. COOH. [CHLORO-PROPIONIC ACID CH3-CHCI-COOH. Dense liquid of sp. gr. 1.28. Boils at 186° C. Prepared from lactyl chloride by OH2, and changed when heated with HOAg, into ClAg and lactic acid. Bromo-propionic acid C3H5BrO2, is solid at - 17° C., and boils at 202° C. From propionic acid by Br2 or from lactic acid by 2BrH. Alcoholic Han changes it into Alanine or AMIDO-PROPIONIC ACID CH3-CH(H2N)-COOH. Crystallizes in tufts of needles, soluble in 5 of water. Quickly heated, into CO2 and ethylamine. Nitrous acid converts it into lactic acid. Propionamide C₃H₅O,H₂N, resembles ACETAMIDE C₂H₃O,H₂N. Melts at 75° C.]

Secondary propyl alcohol C₃H₇OH = CH₃-CHOH-CH₃. "Pseudopropyl alcohol." The OH is placed between two other carbonatoms, as in all secondary alcohols. Isomeric, but differing in properties and results of decomposition. Also called DI-METHYL CARBINOL. Boils at 84° C. Forms definite hydrates. From ISO-PROPYL IODIDE by SILVER acetate, AND from iso-propyl acetate by HOK. On oxydation yields a ketone (not an aldehyde). Thus: CH₃-CHOH-CH₃ minus H₂ = CH₃-CO-CH₃ or Acetone C3H60 (p. 95). Nascent hydrogen H2, changes acetone into secondary propyl alcohol. Acetone, by further oxydation 202 = CO2 + OH2 + ACETIC ACID CH3COOH. [Chlorine may substitute H, atom for atom in acetone. Under the influence of CIH, acetouc may become: MESITYL-OXIDE C6H10O; PHORONE

CoH, O, and MESITYLENE CoH, 12.

Propene C₃H₆, colorless gas, condensable. In coal-gas. With IH forms secondary propyl iodide CH3.CHI.CH3. By nascent H or IH on ALLYL IODIDE C3H3I. Or, by heating HOK with PROPYL IODIDE C3H, I = OH2 + IK + C3H6. Propene glycol (C3H6)"(OH)2, is the third diatomic alcohol. Colorless, oily liquid, of sweet tastc. Boils at 188° C. By contact with Platinum black into LACTIC ACID CH3. CHOH. COOH, and OH2. Gaseous CIH into PROPENE CHLORHYDRIN CH3. CHOH. CH2Cl. The glycol, by distilling PROPENE ACETATE (CH3.COO)2C3H6 with 2KOH = $_{2}\text{CH}_{3}\text{COOK} + (\mathbf{C}_{3}\mathbf{H}_{6})''(\mathbf{0H})_{2}.$

Propene oxide (C3H6)"O, is a volatile liquid, readily soluble in water; boils at 35° C. By aqueous HOK upon propenc chlor-

hydrin.

Propenyl alcohol or Glycerin (C3H5)"(OH)3 is a triatomic alcohol. By substituting 3(OH) for 3H in a PARAFFIN, we obtain a triatomic alcohol. Methenyl alcohol (CH)"(OH), and ethenyl alcohol (C₂H₃)"(OH)₃ are nnknown. But most natural fats are the ethers of propenyl, or glycerides. E.g. PALMITIN (C₂H₅)"(OC₁₆H₃₁O_{.)3} is palmitate of properly. When boiled with 3K(OH) = palmitate of K 3[(C₁₆H₃₁O(OK)] and glycerin. Thesame result in saponification. Glyeerin made originally by heating olive-oil (OLEATE OF PROPENYL) with LEAD-OXIDE and OH,: "lead-plaster" or lead oleate, as an insoluble soap is obtained, and glycerin. Now prepared, by action of snper-heated steam npon stearin of STEARATE OF PROPENYL (C3H3)"(OC18H35O)3 + 3 WATER=glycerin $(C_3H_5)'''(OH)_3$ +STEARIC ACID 3 $[C_{18}H_{35}O.OH]$. Glyeerin is a colorless, viseid liquid, of sp. gr. 1.27. In form of erystals, it melts at 15°.5 °C. Very sweet, does not ferment, but with yeast, gradually, into propionie acid. Heated, it volatilizes in part, slightly darkens, leaves no residue, and evolves pungent vapors of aerolein. As ETHYL ALCOHOL by O, into acetic acid CH3.COOH; ETHENE GLYCOL + O2 into glycollic acid CH₂OH.COOH, so also glycerin by O₂ into glyceric acid C₃H₅O₄ and WATER. Treated with concentrated NO2OH, into GLONOIN or nitro-glycerin CH₂(ONO₂).CH(ONO₂).CH₂(ONO₂), a heavy oily liquid. Explodes by percussion. Sulphoglyceric Acid C3H5(OH)3SO3. PHOSPHO-GLYCERIC ACID in the brain and in yelk of eggs. Monatomie hydroxyl acids when heated in sealed tubes with glyecrin, form WATER, and compound ethers. Thus: MON-ACETIN C₃H₅(OH)₂OC₂H₃O; DI-ACETIN C₃H₅(OH)(OC₂H₃O)₂; TRI-ACETIN C₃H₅(OC₂H₃O)₃. Glycerides this produced. The hydrogen acids can only remove up to two atoms of OH. monochlorhydrin C3H5(OH)2Cl and dichlorhydrin C3H5(OH)Cl2. Only by PCl, can we obtain trichlorhydrin C3H5Cl3. Thus: $C_2H_3(OH)Cl_3 + Cl_5P = POCl_3 + ClH + C_2H_3Cl_3$. [BrH like CIH. III differently; C₆H₁₀O₂(OH)I. Epi-chlorhydrin C₃II,OCl by treating dichlorhydrin with HOK. By heating the mono- or di-chlorhydrins with sodium aleohol, we obtain MON-ETHYLIN C₃H₅(OH)₀C₂H₅ and DI-ETHYLIN C₃H₅(OH)(C₂H₅)₂. Poly-glycerins also exist.]

Allyl compounds. Allyl alcohol $CH_2.CH.CH_2OH = C_3H_5OH.$ Colorless liquid, of pungent odor. Very soluble in alcohol, ether and water. Boils at 103° C. Inflammable primary alcohol. Prep. from allyl oxalate $C_2O_2(OC_3II_5)_2$ by $2H_3N = 0$ XAMIDE $C_2O_2(H_2N)_2 +$ allyl alcohol. Allyl iodide C_3H_5I , is a liquid of sp. gr. 1.78; boils at 100° C. Prep. by distilling propenyl alcohol with phosphorus tetriodide. Thus: $2[(C_3H_5)''(OH)_3] + P_2I_4 = I_2 + 2POH(OH)_2 +$ allyl iodide $2C_3II_5I$. Treated with silver oxalate $C_2O_2(OAg)_2$, yields silver for allyl alcohol valate. By treatment with phosphorie anhydride, allyl alcohol

gives allylene C3H4. Oxygen (by platinum black, or better by distillation with potassium di chromate and sulphuric acid) produces Acrolein or acrylic aldehyde C₃H₄O, and acrylic acid C₃H₄O₂. ACROLEIN CH2-CH-COH, is a thin, colorless, volatile liquid, lighter than water; boils at 52°.2 C. Its vapor is fearfully irritating. By nascent H2 into allylic alcohol. With H3N into OH2 and acrolein-ammonia. Acrylic acid is the first of the acrylic series, of the general formula $C_nH_{2^n-2}O_2$. ACRYLIC ACID C₂H₃COOH = C₃H₄O₂. Colorless liquid of pungent, aromatic odor, soluble in water. Melts at 7°C. Boils at 139°C. By nascent H2 into propionic acid. [Crotonic acid C3H3COOH = C₄H₅O₂. ANGELIC ACID C₄H₇COOH = C₅H₈O₂, in the root of Angelica Archangelica. Hypogæic acid $C_{15}H_{29}COOH = C_{16}H_{30}O_{2}$, as a glyceride in Arachis hypogæa.] [Oleic acid C₁₇H₃₃COOH = C₁₈H₃₄O₂, belongs to the acrylic series. Obtained by the saponification of olein or ter-oleate of propenyl, the fluid portion of most oils and fats. Olein (C₃H₅)(OC₁₈H₃₃O)₃, best exemplified by olive oil, which, below 4° C., deposits solid Palmitin. Oleic acid crystallizes in white needles; melts at 14° C. Sp. gr. 0.898. Neutral to test-paper. Insoluble in water. OLEATES.] Allyl cyanide CNC₃H₅, is found in oil of mustard. Iso-cyanide of allyl NCC3H3, formed by digesting allyl iodide with silver cyanide. Allyl sulpho-cyanide NCSC3H5, chief constituent of oil of mustard. Excites to tears. Boils at 148° C. By H3N into thiosinamin or allyl sulpho-urea CS(H2N)(NH.C3H3). Allyl sulphide S(C₃H₅)₂. In Allium sativum.

Among important tri-carbon compounds, belongs lactic acid, of the same series as glycollic, or oxy-acetic acid. [1. CARBONIC ACID CO(OH)2. 2. GLYCOLLIC ACID CH2OH.COOH.] 3. Lactic acid C₃H₆O₃, or oxy-propionic acid (C₂H₄)"(OH)(COOH). Two Modifications. Ordinary lactic, or methyl-lactic acid $\mathrm{CH_3.CHOH.COOH} = \mathfrak{C}_3 \mathrm{H}_6 \mathfrak{d}_3$. Colorless syrup, of sp. gr. 1.215. Very sour, and soluble in water, alcohol, and ether. Inactive in its relations to polarized light. LACTATES. (C₃H₅O₃)₂Ca,5OH₂. Nodular group of needles, soluble in 9.5 parts of water. (C3H5O3)2Zu,3OH2, slender needles, soluble in 50 of cold water. When lactic acid heated, forms anhydride, or lactide C3H4O2, and di-lactic acid C6H10O3. LACTYL CHLORIDE C3H4OCl2 = C2H1Cl.COCI. Colorless liquid, by water into ClH and chloropropionic acid. Prep. of iso-lactic acid. By fermentation: GLUCOSE $C_6\Pi_{12}O_6=2$ lactic acid. Lactose $C_{12}\dot{H}_{22}O_{11}+OH_2=$ 4 lactic acid. By oxydation of propene glycol. By contact for some days of CII₃ COH + CNH + CHI + 2(OH₂) = CIH₁N + lactic acid.—By HNO2 upon AMIDO-PROPIONIC ACID or alanine. By moist HOAg on chloro-propionic acid Cll3.CHCl.COOH. (And lactic acid by 2111 into propionic acid.)—Sarco-lactic, paralactic, or ethene-lactic acid C₂H₄,OHLCOOH, exists in muscular flesh. Turns the plane of polarization to the left. CALCIUM PARALACTATE, 40H₂, is soluble in 12 of cold water. ZINC PARALACTATE, 20H₂, in thick, shining prisms, soluble in 17 of cold water. Heated to 130°, paralactic acid yields dilactic acid, changed by water into iso-lactic or ordinary lactic acid.

IV. Tetracarbon group C4. Butane C4H10 series.

Butane or Quartane C₄H₁₀. As normal (diethyl), CH₃-CH₂-CH2-CH3 a colorless gas, liquid at oo C. In petroleum. By heating ${}_{2}IC_{2}H_{5} + Zn = I_{2}Zn + C_{3}H_{10}$. As iso-butane (CH)(CH₃)₃, a gas, liquid below - 17°C. Butyl or tetryl alcohol is PROPYL CARBINOL CH3.CH3.CH2.CH2OH boils at 115°C., lighter than water, and but little soluble. Prep. from BUTYL CHLORIDE $C_1H_9C1 + CH_3.COOK = C1K + CH_3.COO(C_4H_9)$. Then: $2[CH_3,COOC_4H_9] + (OH)_0Ba = (CH_3,COO)_0Ba + C_4H_0OH,$ Also from BUTYRIC ALDEHYDE CH, CH, CH, COH, by nascent H, Also from Propenyl Nitrile CaH-CN by nascent He into buty!amin C, H, H, N; the latter into BUTYL NITRITE by NOOH, and distilling the nitrite with HOK. By oxydation into butyric acid CH3.CH2.COOH. [1. FORMIC ACID H.COOH. 2. ACETIC ACID CH3.COOH. 3. PROPIONIC ACID CH3.CH2COOH.] 4. Butyric acid CH3.CH2.CH2.COOH. This acid in juice of muscle. in perspiration; as butyrin or propenyl butyrate in butter. A viscid liquid, of rancid odor, easily soluble in water and in alcohol. Sp. gr. 0.958. Solid at - 12° C.; boils at 163° C. In fermentation of lactose, in presence of chalk, first calcium lactate, and then with evolution of 2CO, and 2H, into ealcium butyrate. 2C₃H₆O₃ = 2CO₂ + 2H₂ + butyric acid C₄H₆O₃ = C.H.OH. CALCIUM BUTYRATE, OH2, shining scales, less soluble in boiling water. ETHYL BUTYRATE C4H3OO.C2H5. PRO-PENYL NITRILE C_3H_7CN , by heating with HOK, $+OH_2=H_3N+$ POTASSIUM-BUTYRATE CH3.CH2CH2.COOK. [ISO-BUTYL ALCOHOL CH3.CH2.HCOH.CH3, in fousel oil. Soluble in 103 parts of water. Boils at 110° C. By oxydation into ISO-BUTYRIC ACID CH(CH2), COOH. SECONDARY BUTYL ALCOHOL OF METHYL ETHYL ALCOHOL CH3C2H, CHOH, a colorless oily liquid, of burning taste and pungent odor. Sp. gr. o. 85; boils below 97° C. At 250° C., into OH, + butene C4H8. Prep. from secondary butyl iodido by HOAg.]

[Erythrite $C_1H_6(OH)_4$ or physite $C_4H_{10}O_4$ is the tetratomic alcohol from which secondary butyl iodide is prepared by heating it with $7HH = 4OH_2 + 3I_2 + C(CH_3)(C_2H_3)HI$. A sugar, crystallizing in transparent prisms, readily soluble. Is found in *Protococcus vulgaris*. Tertiary butyl alcohol $C(CH_3)_3OH$, in rhombic prisms, melting at 25°.5 C. Boils at 82°.5 C. By oxydation into acetic acid and acetone. *Prep.* $CH_3COCl +$

 $(CH_3)_2Zn = ZnO + C(CH_3)_3Cl$. Then: $C(CH_3)_3Cl + OH_2 = ClH$

 $+ C(CH_3)_3OH.$

Malic acid C₂H₃OH(COOH)₂=C₄H₆O₅. OXY-SUCCINIC ACID. Already seen at p. 99, that in ordinary succinic acid, CH2 can exchange both atoms of H for OH, and thus, from mono-bromsuccinic acid we obtain by AgOH, silver bromide and malic acid. Naturally in many acid fruits; apples, gooseberries, Sorbus auenparia, Rumex, &c. Tri-atomic; di-basic. Colorless prisms, deliquescent. Also soluble in alcohol. Loses OH, at 13c° C., and at 175° C. into MALEIC ACID C4H4O4 and FUMARIC ACID C₄H₄O₄ or (CHCOOH)₂. [Fumaric acid into succinic acid by nascent H2.] By reducing agents into succinic acid. Acid and neutral salts. LEAD MALATE insoluble in water. Ammonium ACID MALATE in crystals. CALCIUM MALATE sparingly soluble: acid salt, crystallized from nitric acid; with &OH, Asparagin C2H3(H2N)CO.H2N.COOH is the amide of malic acid. In asparagus, marsh-mallow, &c. In lustrous, rhombic prisms C₄H₈N₂O₃,OH₂. Insoluble in alcohol and ether. By fermentation into ammonium succinate. [ASPARTIC ACID CH(HoN)(COOH). CH₂.COOH may be regarded as amido-succinic acid: by

NO(OH) into Malic acid, $+N_2+OH_2$.]

Tartaric acid $C_2H_2(OH)_2(COOH)_2 = C_4H_6O_6$. Tetratomic and dibasic. Dextro-tartaric acid is the acid of grapes, tamarinds, pine-apples, &c. Transparent, mono-elinic prisms, very soluble in water and in alcohol. Sour: not corrosive. Melts at 135° C. and at 170° C. into inactive mesotartaric acid. Heated to 204° C. it loses OH2 and becomes anhydride C4H4O5. Chars; evolves smell of burnt sugar, carbonizes and burns away without residue. With ${}_{2}\text{KOH} = \text{C}_{2}\text{O}_{2}\text{OH.OK} + \text{CH}_{3}\text{.COOK} + {}_{2}\text{OH}_{2}$. Dissolves Fc₂(OH)₆, and dries to brown, glassy substance: not precipitated by ammonia. Potassium tartrate C₂H₂(OH)₂(COOK)₂, very soluble. By neutralizing the acid salt with CO(O2Ca) as in the preparation of the acid: Potassium acid tartrate C.H. (OH), COOH.COOK, is Cream of tartar. White gritty powder, requiring 180 parts of cold and 6 of boiling water. Argol. Decomposed by heat, carbonizes, inflames, and leaves CO(OK), and charcoal. KOH and NH, in solution, acid remaining in excess, give characteristic, white, crystalline precipitates of C4H1O4 (OH)(OK) and C4H4O4(OH)(OH,N), respectively. Rochelle salt is C.H.O.(ONa)(OK),4aq. In large transparent rhombic prisms, soluble in 12 parts of water. CALCHUM TARTRATE is insoluble: lime-water precipitates tartaric acid. Tartar emetic 2[C1H4O4 (OSb)OK7,OH2, in rhombic octahedra, solublo in 15 of cold and 3 of boiling water. Also with (OAs) instead of (OSb). The basic hydrogen of hydroxyl in tartaric acid is displaceable by one or two alcohol-radicles. Racemic or paratartaric acid crystallizes with one mol. of water, in rhombic prisms. No action

on polarized light. In the grapes of the Vosges, and of the Upper Rhine. Artificially by boiling dibrom-succinic acid $C_2H_2Br_2(COOH)_2$ with ${}^2Ag(OH)$.; it is, however, mixed with inactive tartaric acid.

V. Pentacarbon C₅ group. Pentane C₅H₁₂ series.

Pentane or ethyl propyl $C_5H_{12}=C_2H_5.C_3H_7$. In petroleum. A liquid of sp. gr. o.6, boiling at 37° C. [Also isopentane.] No less than eight pentyl alcohols. Butyl carbinol $CH_2.CH_2$. CH₂CH₃CH₂OH is the normal primary pentyl alcohol. From normal butyl alcohol, a. into CH2.CH2.CH2.CH2.CN; b. into CHa.CHa.CHa.CHa.COOH: c. into VALERIC ALDEHYDE CHa.CHa. CH2.CH2 COH, a limpid, pungent fluid, of sp. gr. 0.82, boiling at 96° C.; and d. into the alcohol by nascent hydrogen. Boils at 135° C. By nascent oxygen into propyl-acetic or normal valeric acid C₄H₉.COOH, the fifth of the fatty acids. Oily liquid, of sp. gr. 0.957; boils at 185° C. Smells like butyric acid. Isobutyl carbinol CH.(CH₃)_o.(C_oH₄OH) is the common amylic alcohol of fermentation, known as fousel-oil. Oily, colorless, mobile liquid, of peculiar odor, and burning aerid taste; sp. gr. 0.825; boils at 130° C. Little soluble in water; very soluble in alcohol and other. Exerts rotatory action on polarized light. Burns with blue flame. By platinum black or nascent Oxygen into iso-valeric acid CHo.CH(CHo)o.COOH. or common valerianic acid. In root of Valerian, Angelica, the berries of Viburnum Opulus, &c. Colorless liquid, of sp. gr. 0.947, boiling at 175°C. Oder of valerian. Burns when inflamed. Iso-valerates of zine and bismuth used in medicine. Iso-pentyl chloride is an inflammable liquid. Iso-pentyl iodide CH.(CH₃)₂.C₂H₄I, heated to 290° C. in sealed tubes, yields decane or diamyl $C_5H_{11}.C_5H_{11}$. Zinc-amylide $(C_5H_{11})_2$ Zu formed at same time, changed by OH, into OZn + 2 mols. of pentane. Amyl-ether C₃H₁₁,O.C₃H₁₁; colorless oily liquid. Amyl acetate, fragrant liquid, with odor of Jargonelle pears. Iso-pentene or amylene C₃H₁₀, is a colorless, mobile liquid, obtained from the iso-butyl alcohol by distilling with Cl. Zn, or P2O5. Iso-pentene glycol C5H10(OH)2. is the only amylenc glycol known. Prepared from the acctate, like the other glycols (p. 96). by distilling with Ba(OH)2. Iso-pentenyl alcohol is amyl glycerin (C, H,)(OH), Dense, colorless liquid, of aromatic taste. Soluble in water.

[Pyro-tartaric acid or methyl-succinic acid CH₃.CH. COOH.CH₂.COOH, by dry distillation of tartaric acid, and by nascent H₂ upon itaconic, citraconic, and mesaconic acids. Small, rhombic prisms, by loss of water into tartaric anhydride

(p. 105).
Uric acid and its derivatives. Uric ACID C₅H₄N₄O₅, a white

crystalline powder, without taste or smell. Requires 10,000 parts of water for solution. Insoluble in alcohol and ether. Soluble without decomposition in hot oil of vitriol. In the urine of men and animals; 0.037 per ceut. in human urine. Serpent's dung consists of uric acid and ammonium urate. In destructive distillation, uric acid yields CO2, CNH, CNOH, CO(OH4N), and a coaly residue rich in N. Di-basic, C, H, N, 0.0H.OK, requires 500 parts of cold water. Sodium unate constitutes "chalkstones." Ammonium urate requires 1000 parts of water for solution. When uric acid is evaporated with NO, OH, a deepred tint is produced, which becomes purple with H₃N (murexid C₈H₄(H₄N)N₅O₆). On heating uric acid with hydrogen iodide, +50H₂, it is resolved into glycocin, +3CO₂ + 3H₃N. Alloxan C4H2N2O4,4OH2 in rectangular prisms, anhydrous at 150° C. By the action of strong nitric acid upon uric acid, urea is formed, but decomposed by the nitrous acid: C₅H₄N₄O₃ + $OH_2 + O = C_4H_2N_2O_4 + CO(NH_2)_2$. It may be regarded as MESOXALYL-UREA, in which mesoxalyl (C3O3) takes the place of H₂. It stains the skin red, and gives a blue color with ferrous salts. Boiled with 2H2N = 2OH2 + MYCOMELIC ACID C4H4N4O2. With dilute acids, into OXALIC ACID and UREA. Its aqueous solution when boiled: 3C4H2N2O4 = ALLOXANTIN C₈H₄N₄O₇ + PARABANIC ACID C₃H₂N₂O₃ + CO₂. Alloxanic acid C4H4N2O5, on boiling with water, + OH2, is resolved into UREA $CO(H_2N)_2 + MESOXALIC$ ACID $C_3O_3(OH)_2$ (p. 99). Mesoxalic acid $+H_2$ = TARTRONIC ACID $C_2H_4O_5 = CH.OH(COOH)_2$, a tri-atomic and di-basic acid, in the same series as MALIC ACID CH.OH.COOH.CH₂.COOH. Parabanic acid C₃H₂N₂O₃ = CO."(HN.CO), or OXALYL-UREA, is formed by the action of nitric acid, and heat upon ALLOXAN or upou URIC ACID: $C_5H_4N_4O_3 + O_2 + 2OH_2 = 2H_3N + 2CO_2 + C_3H_2N_2O_3$. It is di-basic. In presence of alkalies, it takes up water, and is changed into OXALURIC ACID C3H4N2O4. When parabanic acid is neutralized with H₃N and boiled, AMMONIUM OXALIBATE is deposited in crystals on cooling. Alloxantin C₈H₄N₄O₇, 3OH₂, is a product of the reduction of alloxan. 2C4H2N2O4 + SH2 $= OH_2 + S + C_8H_4N_4O_7$. Small colorless prisms. Prolonged action of hydrogen sulphide upon alloxan gives rise to dialuric acid C₄H₄N₂O₄. Easily accomplished by moist solium amalgam. Dialuric acid may be regarded as tartronyl-urea C₁O₁(H₂N)₂. Purpuric acid C₈H₅N₅O₆ as Ammonium Pur-PURATE C_sH₄(H₄N)N₅O₆, or Murexide, is easily formed by heating dry alloxantin with 2H3N at 100° C. Thus: C8H4N4O7 + 2H₂N = C₈H₄(H₄N)N₅O₆,OH₂. Small square prisms, of green metallic lustre, little soluble in water. Allantoin C₄H₆N₄O₄, in brilliant prismatic crystals, soluble in 160 parts of cold water. Contained in the allantoic fluid of the feetal calf.

Artificially by boiling nric acid with lead peroxide and water: $2C_5H_4N_4O_3 + O_2 + 5OH_2 = 2$ urea + 2 oxalic acid + $C_4H_6N_4O_3$. Thionuric acid $C_4H_5N_3SO_6$, as ammonium thionurate is obtained when a solution of alloxan $C_4H_2N_2O_4$ is mixed with a slight excess of $SO(OH)_2$: then ammonia and ammonium carbonate are added, and the whole boiled. When thionuric acid is boiled with water + $OH_2 = SO_2(OH)_2 +$ uramil $C_4H_5N_3O_3$. Then: uramil $C_4H_5N_3O_3 +$ alloxan $C_4H_2N_2O_4 +$ ammonia $H_3N =$ murexid $C_8H_4(H_4N)N_5O_6, OH_2$.

VI. Hexacarbon C₆ group. Hexane C₆H₁₄ series.

Hexane C₆H₁₄ or di-propyl. Occurs as normal CH₃.(CH₂)₄CH₃ in petroleum. Boils at 70° C. From normal PROPYL IODIDE by sodium. Or by 2ClH + Zn on secondary HEXYL 10DIDE. Isohexane, or PROPYL-DIMETHYL-METHANE, boils at 62° C. Methylbutyl carbinol or PRIMARY HEXYL ALCOHOL C₆H₁₃.OH = CH₃(CH₂)₄CH₂0H. Liquid of strongly aromatic odor. Sp. gr. 0.82: boils at 156.6° C. The essential oil of Heracleum giganteum is a mixture of hexyl butyrate and octyl acetate. CAPROIC ALDEHYDE CH. (CH.), COH. Caproic acid or PENTYL FORMIC ACID CH3(CH2), COOH. The sixth of the fatty series, of which formic acid H.COOH is the first. Clear, mobile liquid, of pungent sudorific odor. Sp. gr. 0.895; boils at 205° C. Contained in perspiration; as a glyceride in butter, and largely in coeoanut-oil. Artificially by heating normal pentyl cyanide CH₃(CH₂)₄.CN with KOII solution. Hexene glycol C₆H₁₂(OH)₂ = CH₂OH.(CH₂), CH₂OH. Boils at 207° C. SECONDARY HEXYL ALCOHOL OF METHYL-BUTYL-CARBINOL CH3.C4H CHOH, is a viscid liquid, of pleasant, refreshing odor; boils at 137° C. By ClH, into chloride, and water. Prepared by treating MANNITE $C_0H_0(OH)_0$ with strong HI, we obtain $6OH_0 + 5I_0 + \text{SECONDARY}$ HEXYL IODIDE C₆H₁₃I. The latter, with AgOH gives AgI + ${
m CH_3.C_4H_9.CH0H.}$ When oxydized, into methyl-butyl-ketone ${
m CH_3.CO.C_4H_9.}$ Hexene ${
m C_6H_{12}}$ is obtained from this alcohol.

The hexatomic alcohols and ethers must be included in this group. Mannite $C_6H_8(OH)_6$, in four-sided prisms, easily soluble in water and alcohol; not in ether. Melts at 166° C. Made from manna, an exudation from the ash. Also contained in mushrooms, onions, celery, asparagus, and in various sea-weeds. Glucose also by nascent H_2 into mannite. By oxydation with Platinum black, into mannite acno CH2OH(CHOH)₄COOH; and further by nitric acid into saccharde acid (CHOH)₄(COOH)₂ and oxalic acid. By finning $NO_2(OH)$ into nitro-mannite $C_6H_8(NO_2)_6O_6$. By hydrodic acid into secondary hexyl alcohol. Dulcite is isomeric with mannite. A sugar imported from Madagascar. Melts at 182° C. Yields much acid by oxydation

with nitric acid. Sorbite contains water of crystallization 2[C₆H₈(OH)₆],3OH₂. Melts at 110° C. None of these sugars ferment with yeast, or reduce alkaline cupric solutions. PINITE and QUERCITE, are sugars isomeric with MANNITAN CoH, O(OH)4. Glucose C₆H₁₂O₆, is the aldehyde of mannite, into which it is changed by nascent hydrogen. Dextrose is the common glucose or grape-sugar,—the sugar of fruits. It requires 1.224 parts of water for its solution, and is therefore less sweet than SUCROSE. It crystallizes as $C_6H_{12}O_6$, OH_2 in granular masses. Readily loses this water, and at 170° C. into GLUCOSAN CoH10O5 + OH2, which does not ferment, and is scarcely sweet. Solution of dextrose, reduces solution of cupric salts, when rendered alkaline, and with sulphuric acid forms SULPHO-SACCHARIC ACID C₈H₁₀O₅SO₃. Reduces also salts of Ag, Hg and Au.—CaO, BaO, and PbO form compounds with dextrosc. Unites with NaCl. Browns with KOH. With yeast at 24° C. undergoes vinous fermentation: $C_6H_{12}O_6 = 2CO_2 + 2[C_2H_5(OH)]$. In diabetes abnormally; in the blood, albumin of eggs and in the urine, normally in minute quantities. Artificially, dextrose prepared from starch C18H30O18 by diastase, or boiling with dilute sulphuric acid. First into dextrin and dextrose: C₁₈H₃₀O₁₅ + OH₂ $= 2(C_6H_{10}O_5) + C_6H_{12}O_6$. By further OH_2 , dextrin into dextrosc. Laevulose C₆H₁₂O₆, in honey and many fruits, with dextrose. Fruit-sugar is a mixture of the two: also called invert sugar. Very sweet, uncrystallizable syrup, very soluble in alcohol. Its calcium compound is solid, and separable from dextrose; then decomposed by CO2. Also formed by dilute sulphuric acid and heat from sucrose. {LAEVULOSAN C6H10O5 is the anhydride or oxygen ether. From sucrose by heat at 160° C. = DEXTROSE C6H12O6+LAEVULOSAN, which does not ferment. Inosite C6H12O6, in prisms, resembling Selenite. Not fermentable. In the muscular substance of the heart, and other organs, in beans of various kinds, and in lentils, &c. GALACTOSE C6H12O6, also resembles dextrose, and is obtained from LACTOSE, by heating with dilute sulphurie acid. Glucosides contain glucosan; formed by heating for a length of time, glucoso with various organic acids, and elimination of water. Sucrose C12H22O11 is a di-glucosic alcohol. $2C_6H_{12}O_6 - H_2O = C_{12}H_{22}O_{11}$. Chiefly from Saccharum officinarum. Also in almonds, nuts, coffeebeans, most sweet fruits, &c. As sugar-candy, in 4-sided, oblique-rhombic prisms, with di-hedral summits. "Syrup" boils at 110° C., but reduced to 65°.5 C. in vacuum-boilers. Melts at 160° C. Barley-sugar is amorphous sucrose. Very sweet, as it requires only one-third of its weight of water for solution. Antiseptic. By long boiling, + H2O into laevulose: quickly, by dilute acids. SO4H2, decomposes sucrose, with separation of carbon. Easily oxydized; hence a reducing agent. Does not

brown with alkalies, nor does its solution reduce cupric salts in presence of KOH. Heated to 160° C. into DEXTROSE C6H,2O6 and LAEVULOSAN C6H10O5: at 210° C., into caramel C12H18O6+ By dilute nitric acid, at 50° C., + 30, = H₂O + sac-CHARIC ACID (CHOH), (COOH), : at a boiling heat into OXALIC ACID C₂O₂(COOH), (p. 98). Dissolves CaO, and forms ealcium compounds; also with ClNa. [Melitose C12H22O11.3OH2, from the manna of Eucalyptus.] Lactose C12H22O11,OH2, is milksugar. From whey, in white, translucent, four-sided prisms of great hardness. Requires five to six times its weight of water for solution: insoluble in alcohol and other. Right-handed rotation, like dextrosc. Reduces eupric salts. By dilute SO4H22 into dextrosc. Forms a crimson solution with oil of vitriol. With dilute nitrie acid into MUCIC ACID C, H, (OH), (COOH), soluble in 66 parts of boiling water. Gradually ferments with yeast. With cheese or glutin, into methyl- or ordinary lactic acid CH₃,CHOH.COOH = C₃H₆O₃ (p. 103). Trehalose C₁₂H₂₂O₁₁,2OH₂ from Trehala manna. Mycose C₁₂H₂₂O₁₁,OH₂, from ergot of rye, resembles trehalose. Both are very soluble and very sweet.-Starch C18H20O15, may be regarded as the anhydride or oxygen-ether of a triglucosic alcohol. From ${}_{3}C_{6}H_{12}O_{6}$ minus ${}_{3}OH_{2}=C_{18}H_{30}O_{15}$. Starch, fecula or amylum is most abundantly diffused through seeds, roots, tubers, stems, &c. Varieties of stareh. Sago, from the pith of a palm. Tapioca from Jatropha Manihot. Salep from Orchis mascula. Arrowroot from Maranta arundinacea. A very dilute solution of sodium hydroxide is employed in removing the glutiu from rice, and leaving the starch. Soft, white, glistening powder, destitute of crystalline structure, made up of little rounded and flattened grains, upon each of which a series of depressed parallel rings surrounding a central hilum may be traced. Differ in size and shape; largest in potato-starch, smallest in rice. Insoluble in water, alcohol and ether. Heated with water above 6c° C., the granules swell, burst and form a gelatinous mass (amidin), precipitated by ammoniacal lead acctate, by infusion of galls. With free iodine, starch forms a blue compound: the chief test. Heated to 204° C. into DEXTRIN $C_6H_{10}O_5$, which is used as a substitute for gum arabic. When boiled with very dilute sulphuric acid, first by OH, starch is changed into 2 of DEXTRIN and 1 of DEXTROSE, and the dextrin by further boiling altogether into DEXTROSE C6H12O6. GLYCOGEN C₆H₁₆O₅, is a starell-like substance obtained from the liver of many animals and from the muscles of feetal calves. Soluble in water; solution opalescent. Insoluble in alcohol. Inulin C₈H₁₀O₅, in Inula, Leontodon, Colchieum, Dahlia tubers, &c. Colored brown by iodine. By acids into laevulose. Not precipitated by lead acetate or infusion of galls. Cellulose C18C30O15,

is the basement-tissue of vegetables. Porous in pith; dense in vegetable ivory. Tasteless, insoluble in water and alcohol, unaffeeted by boiling water, as will be understood by the remembrance of the nature of linen and cotton, which may be regarded as eellulose. By strong sulphurie acid into dextrin, and by subsequent boiling with water into dextrose; the acid removable by chalk, and filtration from SO, Ca. Cellulose is not colored by iodine, and is soluble in ammoniated solution of Cuprie oxide. By strong NO₂OH, into pyroxylin or guncotton C₁₈H₂₁(NO₂)₉O₁₅, insoluble in mixed alcohol-ether. Another variety $C_{18}H_{22}(NO_2)_8O_{15}$ is soluble in alcohol-ether. Yet another $C_{18}H_{21}(NO_2)_7O_{15}$, is soluble in glacial acetic acid: the two last used in making eollodion. Reducing agents replace the hydrogen. Arabin, C12H20O10,OH2, as in gum arabie, is isomerie with sucrose. Soluble in cold water, it is precipitated by alcohol. White or pale-yellow, non-erystalline, of smooth conchoidal fracture. It is not precipitated by neutral lead acetate. Mucilage resembles arabin, but is not precipitated by lead acetate. Gum tragacanth is not soluble in water; eliefly composed of bassorin. Cerasin, from Prunus Cerasus, resembles bassorin. [Pectose is contained in the pulp of unripe fleshy fruits, fleshy roots, &c. It is insoluble in water, and changed by aeids into soluble Pectin C₃₂H₄₈O₃₂, such as is contained in ripe currants, gooseberries, &c., and causes the formation of jellies. Separable by alcohol from solution.

To the glucosides belong certain bitter, erystalline substances, diffused through vegetable kingdom, which, by boiling with dilute acids or alkalies (+ OH₂), change into glucose and some other substances. Salicin C₁₃H₁₈O₇. White needles, of bitter taste in bark of Salix, Populus, &e. By SO_4H_2 , deep red. By EMULSION, $+ OH_2 = GLUCOSE C_6H_{12}O_6 + Saligenin C_7H_8O_2$. When distilled with SO₄H₂ and CrO₃, CrO₂(OK)₂, it yields SALICYLIC ALDEHYDE C₆H₄OH.COH. Helicin C₁₃H₁₆O₇, crystalline bitter. By dilute NO2OH upon salicin C13H18O1. Aloin C₁₇H₁₈O₇, yellow needles, the active principle of aloes. Amygdalin C20 H27 NO11,3 OH2 in white, inodorous, slightly bitter seales. Thus by synaptase or emulsion, a species of diastase: ${}_{2}C_{20}H_{27}NO_{11} = GLUCOSE C_{6}H_{12}O_{6} + 2CNH + 4OH_{2} + 4HCOOH$ + 4C₆H₅COH. Populin C₁₃H₁₇(C₇H₅O)O₇ aecompanies salicin in bark of the aspen. Aesculin $\hat{C}_{21}H_{24}O_{13}$, erystalline and fluoreseent. Phlorizin $C_{21}H_{24}O_{10}$, $2OH_2$, silken needles. In root-bark of the cherry, apple, &c. By dilute acids $+ 0H_2 = \text{GLUCOSE}$ C₈H₁₂O₆ + PHLORETIN C₁₅H₁₄C₅. Glycyrrhizin C₂₄H₃₆O₉, unerystallizable sugar of liquorice. Does not ferment. Myronic acid $\mathrm{C_{10}H_{19}NS_2O_{10}}$ as potassium myronate in black mustardseed. By myrosin, into glucose C6H12O6, Potassium hydroxyl SULPHATE SO₂(OH)(OK) and SULPHOCYANIDE OF ALLYL NCC₃H₅S

(p. 103). Chitin $C_9H_{15}NO_6$, forms the elytra and integuments of insects, and the carapaces of crustaceans. By $_2H_2O = C_9H_{12}O_9 + LACTAMIDE C_2H_5(H_2N)O_9$.

The benzene-derivates may also be considered under the Hexyl-group. The hydro-carbons of this series $C_nH_{2^n-6}$, the aromatic group, are analogous to the paraffin series of the

fatty group.

Benzene, Phene or phenyl hydride C_cH_cH_e=C_cH_c, a colorless. limpid liquid, of sp. gr. 0.885 and ethereal odor. Boils at 80°.5 C. Solidifies at 0° C. Solnble in alcohol and ether. A great solvent of fats, oils, resins, sulphur, phosphorus, &c. At a bright-red heat, in absence of air, into H2 + C2H2 + DIPHENYL C₁₂H₁₀, &c. Is contained in the more volatile portions of coaltar oil. Also by heating benzoic acid CgHs. COOH with CaO $= CO(O_sCa) + C_gH_g$. Unites with 3Cl₂ to $C_gH_gCl_g$, a crystalline body. Also with 3ClOH to C6H6(ClOH)3: by potassium hydroxide into 3ClK + phenose C₆H₁₂O₆. Mono-chlorbenzene C.H.Cl, liquid of 1.128 sp. gr. By Cl. Pupon PHENOL C.H.OH. Cyano-benzene CoH, CN is PHENYL CYANIDE, an oily liquid. Also "benzo-nitrile," and obtained by dehydration of AMMONIUM BENZOATE C6H5.COOH4N. Nitro-benzene C6H5(NO2), vellow liquid of aromatic odor. Substitute for oil of bitter almonds in perfumery. Di-nitro-benzene $C_6H_4(NO_2)_2$, in long rhombic prisms. Separates, on cooling, from alcoholic solution of both. Amido-benzene or Phenyl-amin is Anilin C₆H₅(H₂N). Colorless, oily liquid. of sp. gr. 1.036; boils at 184°.5 C. Soluble in 31 parts of cold water. Browns on exposure. Stains deal yellow. With Cl, OCa, in aqueous solution, violet. Powerful base. Prep. a. by boiling indigo with KOH solution: $C_8H_5NO + OH_2 + 4KOH = 2CO(OK)_2 + C_6H_5(H_2N) + 2H_2$. The name from Indigofera anil. b. On the large scale by reducing NITRO-BENZENE C_6H_5 , NO_6 . Thus: $C_6H_5NO_2 + 3H_2 = 2OH_2 + C_6H_5$ H₂N. c. by heating PHENOL C₆H₅.OH, in sealed tubes with $H_3N = OH_2 + C_6H_5H_2N_4 - Di-phenylamin (C_6H_3)_2HN_5$ weak base erystalline. By heating phenylamin hydrochloride with phenylamin. Tri-phenylamin (C₆H₅)₃N.—The anilides contain acid radicles. Thus: acetanilide C₆H₅.H₂N.C₂H₃O. Obtained by heating anilin with acetic acid. Phenyl-carbamide $\mathrm{CO}(\mathrm{H_2N})(\dot{\mathrm{C}}_6\mathrm{H_5HN})$ is phenyl-urea. By passing cyanic acid vapor into anilin. Phenyl-phosphine $\mathrm{C}_6\mathrm{H_5H_2P}$. Benzene-sulphonic acid C₆H₅.SO₃H, by heating benzene with oil of vitriol. 1. Phenol or phenyl alcohol CaH5.OH, is commonly known as carbolic acid. It is a monatomic alcohol. Crystallizes in colorless prisms, of sp. gr. 1.066. Melts at 40° C.: boils at 181°.5 C. Burning taste, antiseptic, poisonous. Soluble in 15 of water: colored violet by ClaFe2, and stains deal of a blue color. Precipitated by aqueous Bromine. With oil of vitriol,

PHENOLSULPHONIC ACID C₆H₄(OH)SO₃H. Obtained from the acid portion of eoal-tar-oil. Also by heating SALICYLIC ACID C_6H_4 .OH.COOH = $CO_2 + C_6H_5$ OH. Also from phenylamin by $NO.OH = N_2 + OH_2 + C_6H_5.OH$. Potassium phenate $C_6H_5.OK$. Phenyl hydrosulphide C₆H₅.SH, is a colorless, mobile, malodorous liquid, of sp. gr. 1.078. By P₂S₅ on C₆H₅.OH. Phenyl sulphide (C₆H₅)₂S, a colorless liquid, of sp. gr. 1.12. [Nitrophenol C_6H_4 . NO_2 .OH, in large yellow prisms. Di-nitro-phenol $C_6H_3(NO_2)_2$.OH, in colorless plates.] Tri-nitro-phenol C_6H_3 (NO₂)₂.OH, is known as picric acid and carbazotic acid. In yellow laminæ, of intensely bitter taste. Sparingly soluble. Yellow dye for silk and wool. A test for K. Prepared from phenol by action of NO₂OH. [2. Pyro-catechin C₆H₄(OH)₂, is a diatomic phenol. In short square prisms, readily soluble in water. By heating methyl-pyrocatcehin with IH = ICH₃ + C₆H₄(OH)₂, Hydro-quinone C₆H₄(OH)₂, colorless, rhombie prisms. Quinone C6H4O2, golden-yellow prisms. Tetrachloroquinone is Chloranil C₆Cl₄O₂.] 3. Pyrogallol C₆H₃(OH), or pyro-gallic acid, is a tri-atomic phenol. Long, flattened prisms, very soluble. Melts at 115° C. At 250° C., with loss of OH, into metagallie acid C₆H₄O₂. Its solution in KOH, absorbs O, browns, and may be employed for estimating O in air. Reduces salts of Au, Ag and Hg. Prep. by heat on gallic acid CaH, (OH)₃COOH. Benzyl alcohol CaH₃.CH₂OH, is a normal aromatic alcohol. Colorless, oily liquid, insoluble in water. Boils at 207° C. By Platinum black into BENZOIC ALDEHYDE CaH, COH, and by aqueous chromic acid into BENZOIC ACID CoH s. CO(OH). Benzoic ether is contained in Balsams of Peru and Tolu. Prep. a. from benzaldehyde by H2. b. from BENZY1. ACETATE $C_6\hat{H}_5.CH_2.OC_2H_3O + KOH = C_2\hat{H}_3O.OK + BENZYL$ ALCOHOL C₅H₅.CH₂OH.—Benzoic aldehyde C₅H₅.COH. knewn as "bitter-almond oil." Colorless liquid, of agreeable odor. Sp. gr. 1.05: boils at 180° C. Soluble in 30 parts of water. Absorbs O and becomes changed into BENZOIC ACID CaH3. COOH. Heated with KOH, H2 set free, and potassium benzoate formed. With alkaline-hydroxyl sulphites, forms erystalline compounds. With sodium amalgam and water into BENZYL ALCOHOL C.H. CH.OH. With Cl₅P into Benzal Chloride C₆H₅.CHCl₂. By H₃N into hydrobenzamide, a neutral body, and this by boiling KOII into an isomeric basic compound amarine (C,H6)3N2. All aromatic aldeligdes act similarly, and thus distinguished from the fatty aldehydes. Salicylic aldehyde C,H,(OH),COH, in flowers of Oil of meadow-sweet. Colorless, fragrant oil, of sp. gr. 1.172. Somewhat soluble in water, and gives violet color with ferrie salts. Heated with KOH into H .+ POTASSIUM SALICYLATE C₆H₄.OH.COOK. By nascent H₂ into saligenin. Prep. by oxydizing saligenin C.H.OH.CH.OH, or its glucosides, saligin

and populin (p. 111). Also by chloroform on alkaline solntion of phenol. $C_6H_5.OH + CHCl_3 + OH_2 = 3ClH + C_6H_4.0H.COH$. Benzoic acid C.H. COOH. Light, flexible needles. Melts at 120° C; sublimes at 145° C. Soluble in 200 of cold, and 15 of boiling water. Basic ferric benzoate is decomposed by ClH, leaving shiny crystals of benzoic acid undissolved in the yellow ferric chloride solution. Calcinm benzoate by heat, gives BEN-ZOPHENONE CoH, CO CoH, the ketone of benzoic acid, and CO(O2Ca). Prep. a. by heating gnm benzoin, benzoic acid sublimes. b. by OH, on BENZOYL CHLORIDE C.H.COCl. c. by boiling the nitrile with acids or alkalies; C₆H₅CN + 2OH₂ = $H_3N + C_6H_5.000H$. d. by oxydizing Benzyl Alcohol: $C_6H_5.CH_2OH_2 + O_2 = OH_2 + C_6H_5.C00H$. e. by oxydizing BENZ-ALDEHYDE C_6H_5 . $COH + O = C_6H_5$. COOH. f. from Bromoben-ZENE by Na₂ + CO₂ = BrNa + C₂H₅ COONa. Benzoyl chloride C.H. COCI, colorless liquid of suffocating odor. By Cl. P upon benzoic acid BENZOYL CYANIDE CaH, COCN, by distilling the chloride with CNK. In large scales. Benzoic oxide (C, H, O), O, in oblique prisms, slowly by boiling water into benzoic acid, $C_6H_5COCl + C_6H_5CO.OK = CIK + (C_7H_5O)_2O.$ Thiobenzoic acid C.H. CO.SH. Benzamide C.H. CO.H.N, by aqueous H.N npon benzoyl chloride. Amido-benzoic acid C6H4(H2N)COOH, by reduction of nitro-benzoic acid CaH4(NO2)COOH with Sn + 2ClH.—Benzamid-acetic acid or hippuric acid CH₂.C₂H₃O.HN. COOH = C₉H₃NO₃ Or "benzoyl-glycocin." Occurs in the urine of cows, horses, &c. By evaporating fresh cow's nrine, to which lime has been added, and adding CIH to the concentrated liquor, hippuric acid crystallizes on cooling. When benzoic acid is taken internally, it is found in the urine as hippnric acid. Rhombic prisms, soluble in 600 of cold water. Acid, bitter, fusible: leaves a coaly residue. By boiling with ClH, assimilation of OH2, into BENZOIC ACID C.H.O.OH + AMIDACETIC or GLYCOCIN CH, (H, N)COOH. Hippurate of ferric, cream-colored. Heated with HOK, gives off H3N and benzene. Mineral acids separate hippuric acid. NOOH converts hippuric acid into OH2 + N2 + BENZO-GLYCOLLIC ACID CoHgO4: and boiling water (+ OH2) changes benzo-glycollic acid into BENZOIC ACID C,H,O.OH and GLYCOLLIC ACID CH,OH COOH. Prep. by $2C_{2}H_{2}OCl + z_{1}NC_{2}GLYCOCIN (CH_{2},H_{2}N.COO)_{0}Zn = Cl_{2}Z_{1}^{2} + 2$ BENZAMID-ACETIC ACID.

Tyrosin $C_9H_{11}NO_3$ has the composition of ONY-PHENYL-AMIDO-PROPIONIC ACID C_6H_4 -OH. $C_2H_3(H_2N)$.COOH. In old cheese, $\tau\nu\rho\delta s$. In the spleeu, panereas and liver. By boiling horn with dilute sulphuric acid, neutralizing with CaO, and precipitation by acetic acid. In slender needles, soluble in 150 of hot water; insoluble in ether. Unites with ClH; its sulpho-acid colored violet by ferric salts. Toluene, C_7H_8 , homologous with benzene,

is methyl-benzene C6H5.CH3. Together with benzene in light coal-tar-oil. Limpid liquid, of sp. gr. \circ .88. With oxydizing agents yields benzoic acid. Artificially: $C_6H_5Br+CH_3I+Na_2$ $= BrNa + INa + C_6H_5.CH_3 = \textbf{C}_7\textbf{H}_8. \quad Also \ by \ nascent \ C_6H_6 + CH_4 = H_2 + \textbf{C}_7\textbf{H}_8. \quad Chloro-toluene \ C_6H_1Cl.CH_3. \quad Toluidin$ C₆H₄.H₂N.CH₃ is homologous with phenyl-amin. Commercial anilin always contains toluidin, and the formation of ROSANILIN C20H17N3 can be accounted for by the following equation: $C_6H_5.H_2N + 2C_7H_7.H_2N = 4H_2 + rosanilin C_{20}H_{17}N_3$. Anilin reds are salts of rosanilin: the latter being colorless. Anilinblue is hydrochloride of Triphenyl-Rosanilin C20H14(C6H5)3 N₃ClH. By heating rosanilin with ethyl iodide, we obtain Hofmann's violet, hydriodide of triethyl-rosanilin $\mathrm{C}_{20}\mathrm{H}_{14}$ (C2H5)3N3.IH. Anilin-green is an aldehyde-green. Nitrous acid 3(NO.OH) converts rosanilin into 3N2+3OH2+ aurin $C_{20}H_{14}O_3$. Anisol is methyl phenate $C_7H_8O=C_6H_5(OCH_3)$. Colorless, mobile liquid, of aromatic odor. Boils at 152° C. Cresol is tolyl alcohol C6H4.CH3.OH. Occurs together with phenol in coal- and wood-tar. Separated by fractional distillation. By long heating with KOH into POTASSIUM SALICYLATE. Xylyl alcohol C₈H₉OH or C₆H₄.CH₃.CH₂OH, is the homologue of benzyl alcohol. It is obtained from the aldehyde. Needles, sparingly soluble. Toluic aldehyde C₆H₄.CH₃.COH. Oily liquid, with odor of pepper. Salicylic aldehyde C₆H₄.OH.COH. Salicylic acid C6H4.OH.COOH is ORTHO-OXY-BENZOIC ACID C₇H₆O₃. In the flowers of Spiraa ulmaria, and as methyl salicylate in oil of winter-green. Little soluble in cold water, crystallizing in minute needles from boiling water. It melts at 155° C., and is resolved by heat into CO2 and PHENOL C6H5.OH. Gives deep violet color to ferric salts. Good antiseptic. Prep. by heating sodium with Phenol C_6H_50 and $CO_2=$ hydrogen free + sodium salicylate $C_6H_4.OH.COONa$. Also by oxydation of salicylic aldehyde. Also by NO.OH upon AMIDO-BENZOIC ACID $C_6H_1H_2N$). $COOH = OH_2 + N_2 + SALICYLIC$ ACID C_6H_4 . OH. COOH. OXY-SALICYLIC ACID C₆H₃·(OH)₂COOH, in shining needles. Gallic acid or di-oxy-salicylic acid CaH2(OH)3COOH in gall-nuts (Quercus infectoria), tea, sumach, divi-divi, &c. By boiling Gallo-Tannic acid with acids or alkalies: $+ OH_2 = 2$ GALLIC ACID C, H₆O₅. Mono-basic; tetratomic. With OH₂, in silken needles, soluble in 100 of cold and 3 of boiling water. Melts at 200° C., and by further heat into CO₂ and pyro-gallol C₆H₃(OH)₃. Reduces salts of Ag and Au. Gives blue-black precipitate with Cl₅Fe₂. May be obtained from DI-10DO-SALICYLIC ACID with ('()(1)Na)2. -Gallo-tannic acid or tannin C14II110O9 is di-gallic acid minus OH_2 . $C_6H_2(OH)_3 CO.0 C_6H_2(OH)_2 COOH$. In unt-galls, sumach, &c. From nut-galls by aqueous ether: tannin in the water, and the gallic acid in the other. On evaporation,

a yellowish powder, very soluble in water. Astringent; bitter. Reddens litmus. Precipitates gelatin, albumin, many alkaloids. &c. Ferrie tanuate, a bluish-black precipitate, is the basis of common ink. Decomposes at 250° C., with formation of pyrogallol. By dilute acids + OH, into 2 mols, of gallie acid. Kinic acid CaHa (OH), COOII, is mono-basic, pentatomic. In cinchona bark. Colorless prisms, easily soluble. By heating with 2IH = 40H₂ + I₂ + benzoic acid. Dimethyl-benzene or xylene C_BH₁₀ = C₆H₄ (CH₃)₂ is the homologue of BENZENE C₆H₆ and TOLUENE C, H, Colorless, volatile liquid. Several isomerie modifications. Dimethyl anilin CaH, (CH3). N. Boils at 192° C. Dimethyl phenol $C_8H_{10}O = C_8H_{0}OII = C_6H_{3}\cdot (CH_{3})_{2}\cdot OH$. Also, XYLENOL. Phenyl-propyl alcohol $\ddot{C}_9H_{11}OH = \ddot{C}_6H_5.(\ddot{C}H_2)_3.OH$. By nascent hydrogen on CINNAMIC ALCOHOL CaHaOH. Phthalic aldehyde $C_8H_6O_2=C_6H_4(COH)_2$. From Phthalyl Chloride C_6H_4 (COCI), by nascent H. In colorless tables. Phthalic acid C.H. (COOH)2, in prisms, little soluble in cold water. Melts at 185°C. By heat into water and PHTHALIC ANHYDRIDE C₆H₄(CO)₆O. By action of 40, upon napththalene C₁₀H₈ = OXALIC ACID + PHIHALIC ACID. When CoH4(COOH), is heated with excess of Calcium hydroxide, we obtain BENZENE CaHa and 2[CO(O2Ca)]; but when 2[C₆H₄(COOH)₂] are heated with (OH)₂Ca, CALCIUM BENZOATE (C.H.COO), Ca results, together with 2OH, + 2CO2. [Mellitio acid C6(COOH)6, in colorless needles, fusible; very stable. Mellite or "Honcy-stone" is mellitate of aluminum. zonic acid C₃O₆H₂(COOH)₂, formed by the action of water upon C2O2K2. Croconic acid C5H2O2 by action of boiling on solution of potassium rhodizonate.] Citric acid C₆H₈O₇ = C₃H₄(OH) (COOH)3, crystallizes with OH2 in trimetric prisms from a cold solution. Very soluble, of pleasant sour taste. Tetratomic, tribasic. Prevents precipitation of ferric by ammonia. If mixed with tartarie acid, in solution detected by potassium acetate. On boiling eitric acid with lime-water in slight excess, caleium citrate is precipitated white, insoluble in KOH. With a ferment of putrid flesh, yields butyric acid ehicfly, and succinie acid. Gently heated with SO₄II₂, gives off torrents of CO. Heated with POTASSIUM HYDROXIDE: 4KOH + citrie acid = C.O. (OK), + 2(CH₃,COOK) + 3OH₂. Salts of Ba, Sr, Ca, Pb and Ag insoluble. Found in lemon- and lime-juice. Clear liquor neutralized with chalk, and the calcium citrate decomposed by SO4H2.

VII. Heptane series. Normal heptane $C_7H_{16}=CH_3, (CH_2)_5$. CH_3 , liquid of sp. gr. \circ 712, is contained in petroleums. Heptyl alcohol or cannthylic alcohol $CH_3, (CH_2)_5, CH_2, OII$, is a colorless, oily liquid. From heptyl aldehyde $CH_3, (CH_2)_5, COH_3$ by moist sodium amalgam. Enanthylic acid $C_7H_1O_2$ is the

seventh of the fatty acids (p. 85).

VIII. Ootano series. Normal octane C₈H₁₈ = CH₃(CH₂)₆CH₃,

boils at 124° C. Octyl alcohol C_7H_{15} . CH_2OH , a colorless oily liquid, of sp. gr. 0.830. Is contained in the seed of Heracleum sphondylium, both uncombined and as octyl acetate, and as octyl butyrate in the seeds of Pastinuca sativa. Artificially from RICINOLEIG ACID $C_{18}H_{34}O_3 + 2HOK = POTASSIUM SEBATE C_{10}H_{16}O_2$ (OK)₂ + H₂ + octyl alcohol C_7H_{15} . CH_2OH . Caprylic acid C_7H_{15} .COOH, of faint, unpleasant odor, is found as glyceride in butter, and in cocoa-nut-oil.

IX. Nonane series. Normal nonane $C_0H_{20} = CH_3(CH_2)_7CH_3$, boils at 136° C. Sp. gr. 0.741. Nonyl alcohol $C_8H_{17}.CH_2OH$,

boils at 200° C.

X. Decane series. Normal decane $C_{10}H_{22} = CH_3(CH_2)_8CH_3$, of sp. gr. 0.757, boils at 160° C. Decyl alcohol $C_{10}H_{21}OH = C_9H_{19}.CH_2OH$ boils at 210° C. Rutic or capric acid $C_9H_{19}COOH$, as a glyceride in butter and in cocoa-nut-oil. Also from amyl rutate in the fonsel oil of the Scotch distilleries. Crystalline.

XI. Endecane series. Endecane C11H24. XII. Dodecane series. Dodecane C₁₂II₂₆. LAURIC ACID C₁₁H₂₃.COOH, from alcohol, in silken needles. As a glyceride in fat of Lyurus nobilis and of Pichurim beans. By saponification with potassium hydroxide, and decomposition of the soap with tarturic acid. XIII. Tridecane series. Tridecane C₁₃H₂₈. XIV. Tetradecane series. Tetradecane C14H30. MYRISTIC ACID C13H27.COOH, in white, lustrous laminæ, which melt at 53°.8 C. Very soluble in hot alcohol. As a glyceride, MYRISTIN (C14H27O)3O3C3H3 in nutmeg-butter and in Otoba fat. XV. Pentadecane series. Pentadecane $C_{13}H_{32}$. XVI. Hexdecane series. Hexdecane $C_{16}H_{34}$. Hexdecyl alcohol $C_{16}H_{33}$.OH = $C_{15}H_{31}$.CH₂OH. ethal. As obtained from spermaceti found in cavities in the head of Physeter macrocephalus. It consists of CETYL OF HEXDECYL PALMITATE $C_{16}H_{31}O.OC_{16}H_{33}$: when fused with KOH = POTAS-SIUM PALMITATE $C_{16}H_{31}O.OK$ + CETYL ALCOHOL $C_{16}H_{33}OH$. White crystalline mass, melts at 50° C. Tasteless and insoluble. When heated with $KOH = 2H_2 + POTASSIUM PAL-$ MITATE $C_{16}H_{31}O.OK$. Palmitic acid $C_{16}H_{32}\tilde{O}_2=C_{15}H_{31}COOH$, is the 16th of the fatty acid series. Occurs as a glyceride in many fats. Most largely in palm-oil from Elais quianensis, in Chinese tallow, and Japan wax, as tri-palmitin (C16 H31 O.O)3. C3H3. Also as cetyl palmitate (spermaceti). Artificially by melting oleic acid $C_{18}H_{31}O_2$ (p. 103) with 2KOH = H_2 + CH₃.COOK + C₁₆H₃₁O.OK. Soluble in beiling alcohol. Melts at 620° C. May be distilled. Mono- DI- and TRI-PALMITIN.

XVII. Margaric acid $C_{17}H_{33}$.OH, was supposed to be intermediate between palmitic and stearic acids. As margarate of potassium $C_{17}H_{33}O.OK + NH_3$ by action of cervi. Cyanide $CNC_{18}H_{33} + KOH + OH_2$. XVIII. Stearic acid $C_{18}H_{35}O.OII$, in macroous lamino, of acid reaction. Melts at 69° C. Tri-

STEARIN (C18H35O.O)3C3H5, a glyceride in most solid fats, as in beef and mutton-suet. Soaps eousist of mixtures of sodium (or potassium) palmitates, stearates, oleates, &c. They are made by saponifying palm-oil, tallow, &c. Sodium-soaps are hard; potassium soaps soft, and contain great excess of alkali. XX. Arachidic acid CooH300.0H, in small seales, by saponifying the oil of Arachis hypogaa. XXII. Behenic acid C22H43O.OH, melts at 76° C. By saponifying the oil from the fruit of Moringa Nux Behen. XXVII. Cerotyl alcohol $C_{27}H_{55}OH = C_{26}H_{53}$. CH₂OH. As purified by ether, a wax-like substance, melting at 97° C. Chinese wax is ceryl cerotate C2-H53O.OC2-H55. When heated with KOH = POTASSIUM CEROTATE C27H53O.OK + cerotyl alcohol. CEROTIC ACID Co. H53O.OH, is the chief eonstituent of cerin, the portion of bees-wax which is soluble in boiling alcohol, and is obtainable by fusing early eerotate, which melts at 82° C., with KOH, and decomposing with an acid. Melts at 78° C., and distils. XXX. Myricyl alcohol C₃₀H₆₁.OH = C₂₉H₅₉.CH₂OH, of silken lustre, is the highest known member of the series. Myricin, or myricyl palmitate C₁₆H₃₁O.OC₃₀H₆₁, is that portion of bees-wax which is insoluble in boiling alcohol. By fusion with KOH, into potassium palmitate and myricyl alcohol. Melissic acid, C30H59O.OH, melts at 89° C. The highest known member of the fatty series, commencing with FORMIC ACID H.COOH (p. 85). Obtained by heating myricyl alcohol with KOH = 2H₂ + POTASSIUM MELISSATE C₃₀H₅₀O.OK. Decomposed by acids.

Naphthalene group. Naphthalene $C_{10}H_s$, in large, eolorless brilliant erystalline plates, with odor reminding of narcissus. Melts at 79°.2 C.: boils at 218° C. Burns with red, sooty flame. Soluble in alcohol and ether. Forms additive compounds with Cl, Br, &c. Contained in last portion of oily product obtained from coal-tar. Also produced by decomposition of benzene, toluene, &c. Thus: $4C_7H_8 = 3C_6H_6 + 3H_2 + C_{10}H_8$. Nitronaphthalene $C_{10}H_7NO_2$. Naphthalene $C_{10}H_7NO_2$. Naphthalene $C_{10}H_7NO_3$, in needles. Naphthalene-sulphonic acid $C_{10}H_7SO_3H$, crystalline, deliqueseent. Naphthiol $C_{10}H_7OH$, colorless prisms; violet with chlorido of lime. Naphthoquinone $C_{10}H_6O_2$, in large, sulphur-yellow tables.

Phenanthrene group. Phenanthrene $C_{14}H_{10}$, in colorless, lustrous laminæ. Contained in the portion of coal-tar, which boils between 320° and 360° C. Anthracene $C_{14}H_{10}$, in colorless tables, little soluble in alcohol and ether. Melts at 215° C. and distils above 360° C. Both phenanthrene and anthracene contain benzene residues; $C_{6}H_{4}$. CH.CH. $C_{6}H_{4}$. Di-bromanthracene $C_{14}H_{5}Br_{2}$ in golden-yellow needles. By the action of Bromine

on anthracene in CS₂. Anthrol C₁₄H₉.OH. Anthraquinone $C_{14}H_8O_2 = C_6H_4.CO.CO.C_6H_4$, in shiny, yellow needles. Sublimes. Not reduced by SO(OH)₂. By oxydation of anthracene. Di-bromanthraquinone C₁₄H₆Br₂O₂. In yellow needles. Obtained by heating anthraquinone with Bromine. By heating with 2KOH at 150° C., into alizarin C14H6(OH)2O2. Anthraquinone-sulphonic acid $C_{14}H_7O_2SO_3H$, and $C_{14}H_6O_2(SO_3H)_2$, by heating anthraquinone with SO2(OH)2 at 255° C. Alizarin C₁₄H₆(OH)₂O₂, in orange-colored needles, forming purple solution with alkalies. Aluminum and tin salts throw down red precipitates of madder-lakes. Alizarin, from the red coloring matter of Rubia tinctorum; contains RUBERYTHRIC ACID $C_{26}H_{28}O_{14}$, which by water (+20H₂) is resolved into 2 DEX-TROSE and alizarin or garancin. Now prepared artificially as above, or cheaper, from $C_{14}H_6O_2(SO_3H)_2$ by fusion with KOH, solution in water, and precipitation of the alizarin by ClH. Purpurin C₁₄H₅(OH)₃O₂ occurs in old madder-roots together with alizarin. Like alizarin, it is reduced to anthracene, by heating with zinc-dust.

Destructive distillation. Among the products of the distillation of wood and resins must be mentioned Kreasote C₈H₁₀O₂. Sp. gr. 1.057. It is to kreasote that wood-smoke owes its antiseptic properties. It is contained in the heavier portions of the oil obtained from wood-tar. It is a colorless, oily liquid, which boils at 203° C. Easily inflamed; burns with a smoky flame. Of pungent odor and burning taste. Little soluble in water; very soluble in acctic acid, alcohol and ether. Coagulates albumin (p. 126) and is the best antiseptic. Phenol or Carbolic ACID C.H.OH, is the common substitute for genuine kreasote.

Terpenes and Camphors. Oil of turpentine C10H16, a colorless, mobile liquid, of aromatic odor, insoluble in water, but soluble in absolute alcohol, ether, benzene and carbonic sulphide. A solvent of phosphorus, sulphur, iodine, bromine, oils, resins (varnishes). Many varieties: isomeric and polymeric. In conifers generally. Forms Hydrates; C10H10,2OH2, and C₁₀H₁₆,3OH₂. By repeated distillation with a little sulphuric acid, into TEREBENE ConHig, boiling at 160° C., and Colorhene C₂₀H₃₂, boiling at a high temperature. Inflames with Chlorine. Unites with 2ClH. CYMENE OF METHYL-PROPYL-BENZENE Coll. (CH₃)(C₃H₇), is made from turpentiue, showing the latter to be a hydride of cumene. By oxydation, turpentine yields acids: formic, acetic, butyric, oxalic, TEREBIO C. II, O, TOLUIC Call, (CH₃)COOH, and TEREPHTHALIC C₀H₄(COOH)₂. Essential oils. Either hydrocarbons isomeric or polymeric with oil of turpentine, or of a mixture of these with compounds of C, H and O. Oil of lemons, from the rind of the fruit of Citrus Limonum, consists chiefly of CITRENE C₁₀H 6. Similar oils from Oils of Neroli, Bergamot, Citron, Lime, Orange, &c. Thyme, Valerian, Chamomile, Juniper, &c. Oils of Capivi and Cubebs, polymeric: C20 H32. Mixed with a terpene, we have valeric acid in oil of Valerian. pelargonic acid in oil of Pelargonium, EUODIC ALDEHYDE C₁₀H₂₁COH in oil of Ruta. Some volatile oils consist of aldehydes, as oils of Bitter Almonds, Cinnamon and Cassia. They are all soluble in alcohol and ether, and produce a greasy stain upon paper, disappearing when heated. Eleoptene is the liquid, and stearoptene the solid portion of an essential oil. None of these oils saponify. Camphors contain 10 atoms of earbon. Laurel camphor C₁₀H₁₆O, a colorless, translucent mass of sp. gr. o 985. Melts at 175° C., and sublimes at 204° C. Readily soluble in alcohol (tincture). By heating with P₂O₅, into cumene C₁₀H₁₄ + OH₂. In Laurus Camphora. Also artificially, as from turpentine, by Mn₂O₆(OK)₂. The essential oils of Lavender, Marjoram, Rosemary and Sage contain camphor. Absinthol C₁₀H₁₀O, from Artemisia Absinthium is a liquid camphor. Cam-PHORIC ACID C₈H₁₄(COOH)₂, in colorless laminæ. By continued boiling of camphor with nitric acid. Borneo-camphor $C_{10}H_{18}O$, melts at 108° C., and boils at 212° C. It is an alcohol $C_{10}H_{17}OH$, vielding compound ethers. Obtained artificially by heating laurel camphor with sodium (sodium borneol CieHiz.ONa), or alcoholic HOK. Occurs in Dryabalanops Camphora. Menthol C₁₀H₁₀OH, in oil of Mentha piperita, occurs together with a terpene.

Resins and Balsams. Colophony or common rosin consists principally of sylvic acid $C_{20}H_{30}O_2$. It is monobasic, and crystallizes from alcohol in laminæ. Lac is harder than resin, and known as stick-seed- and shel-lac. Copal, Mastic, Sandarac, Dammar, and Dragon's blood are also resins. Amber is a fossil resin.—Caoutenoue is the dried milky juice of species of Fieus, Euphorbia and other trees. Solnble in petroleum, benzene, &c. Little affected by chemicals. By destructive distillation yields two polymeric bodies: Isoprene C_3H_8 , and Caoutchin $C_{10}H_{16}$. With Sulphur, Caoutehoue gives vulcanized India Rubber, and Ebonite. Gutta percha, from Isonandra Gutta, is harder than caoutehoue, but very similar. A good insulator of electricity. By destructive distillation yields Isoprene, Caoutehin and Heveene, polymeric hydrocarbons. Balsams are mixtures of

resins with volatile oils.

Coloring matters. Indigotin $C_{16}H_{10}N_2O_2$, in dark-blue needles, may be obtained by subliming commercial indigo. It does not exist in Indigofera Anil ready formed, but as a GLUCOSIDE $C_{26}H_{31}NO_{17}$, which, by boiling with dilute acids, yields INDIGILUCIN $C_6H_{10}O_6$ and INDIGOTIN $C_{16}H_{10}N_2O_2$. Thus; ${}_2C_{26}H_{31}NO_{17}$

 $+4OH_2 = 6$ indigluein + indigotin. Indigo-white $C_{16}H_{12}N_2O_2$ is changed into indigotin by the air or oxydizing agents. Indigosulphonic acid C16H9N2O2,SO3H, by heating indigo with sulphuric acid. Isatin CsH3NO2, in yellowish-red prisms, by heating indigo with nitrie acid. See Phenyl-amin C6H5.H2N, p. 112. Indigo related to benzene group (p. 112). Carthamin C₁₁H₁₅O₂, as a dark-red powder used for dyeing silk, is obtained from the petals of Carthamus tinctorius. Alizarin C₁₄H₆(OH)₂O₂ lias been already described at p. 119. **Hæmatoxylin** $C_{16}H_{11}O_6$, 30H₂ in Hæmatoxylon. Pale-yellow prisms. Carminic acid C₁₇H₁₈O₁₀, in Coccus Cacti most largely, and in the flowers of Monarda didyma. Fine red powder, soluble in water and aleohol. Di-basic. Brazilin $C_{22}H_{18}O_7$, in small yellow prisms, crimson by alkalies. Curcumin $C_{10}H_{16}O_3$, in turmeric. Orange erystals, browned by alkalies. Euxanthic acid C19H16O10, in Purree or Indian Yellow, as magnesium euxanthate. Shiny, yellow prisms. Chlorophyll is leaf-green. Soluble in alcohol and in ClH.

Alkaloids.

They are all derivatives of ammonia. The monamines, derived from a single molecule of ammonia, may contain one, two or three univalent alcohol-radicles in exchange for 1, 2, or 3 atoms of Hydrogen: primary, secondary, and tertiary. They expel ammonia from its salts, when heated with them, and form double salts with platinic chloride, Aurie chloride, &c. They can also replace hydrogen in the ammonium of alums. PRIMARY AMINES, into corresponding aleohols by NO.OH. Thus: $CH_3(H_2N) + NO.OH = OH_2 + N_2 + CH_3OH$. Thus, we have a means of passing from a lower into a higher alcohol series. Ethenyl nitrile $C_2H_3N + 2H_2 = \text{ethylamin } (CH_2CH_3)H_2N, \text{ and}$ ethylamin + NO.OH = OH₂ + N₂ + CH₂CH₃OH. SECONDARY AMINES, by NO.OH into WATER, and nitroso-compounds. Thus: di-methylamine (CH₃)₂HN + NO.OH = Water + nitrosodimethylamin (CH)2NO.N. TERTIARY AMINES are searcely touched by nitrous acid. Pyridine bases, CnH2n-5N, are metameric with phenylamin C₆H₅.H₂N, and its homologues, p. 112. They are contained in coal-tar, naphtha, and in Dippel's oil, which is obtained by the destructive distillation of bones. All liquid, and react as tertiary monamines. Pyridin U.H.N. Picolin C₆H₇N; boils at 133° C. Strongly alkaline, and forms crystalline salts. Lutidin C₇H₉N. Collidin C₈H₁₁N. Parvolin $C_9H_{13}N$. Coridin $C_{10}H_{15}N$. Rubidin $C_{11}H_{17}N$. Viridin $C_{12}H_{19}N$. Chinolin bases $C_0H_{29-11}N$. By distillation of quinin, cinelionin, with KOH. Chinolin Coli, N. Lepidin Coll, N. Cryptidin Cullin N. Leucolin, contained in coal-tar-oil, is isomeric

with ehinolin. Heated with AMYL TODIDE C5H11I, chinolin forms C₉H₇.C₅H₁₁NI, which is changed by heating with KOH into cyanin C28H25NI, a dye of blue color. Conin C.H.N $= (C_o H_{10})''HN$, in the seeds, &c., of Conium maculatum. By distillation with KOH. Colorless, oily liquid, of stupefying odor, browning on exposure. Sp. gr. 0.89. Boils at 1680 C. Very poisonous. Temporary stain upon paper. Slightly soluble in water; freely in alcohol and other. Vapor inflammable. A secondary monamine. METHYL CONIN CH3. C. H14. N. also accompanies conin. With ethyl iodide, conin forms C.H. C₂H₅.N.C₂H₅I, and this, by AgOH into a soluble base. (Cox-HYDRIN C₈H₁₄.H₂NO, accompanies conin.) Nicotin (C₅H₇)₂"N₂, $= C_{10}H_{14}N_2$. In the sceds and leaves of Nicotiana tabacum. united with malic and citric acids. Also in tobacco smoke. Maryland and Hayannah tobacco contain about 2 per cent. Colorless, oily liquid, irritating, and odorous of tobacco. Sp. gr. 1.048. Boils at 249° C. Very soluble in water, alcohol and ether. A fearful poison. With Cl, a red color. With I a rnby-red. Spartein C₁₅H₂₆N₂. Colorless liquid, alkaline, sparingly soluble, bitter, narcotic. Creatin C₄H₉N₃O₂,OH₂, in lustrous prisms, neutral, bitter. In juice of flesh. Artificially by union of CYANAMIDE C(HN)₂ with METHYL-GLYCOCIN OF SARCOSIN CH₃.HN.CH₃.COOH. By boiling with water, into trea and SARCOSIN. By abstraction of water, as when heated with acids, into creatinin C₄H₇N₃O. Creatinin constitutes 0.25 per cent. of the urine. It crystallizes in rhombic prisms, expels H₃N from its salts, and forms salts with acids. Guanin C.H.N.O. a white powder, soluble in ClH. By oxydation into GUAXIDIN CH, N, and PARABANIC ACID C, H, N, O, p. 107. Is contained in the pancreatic juice of mammals and largely in guano. Xanthin C5H4N4O2, in certain calculi; in the blood and mine, and in the liver. Artificially by moist sodium amalgam upon unic ACID C₅H₄N₄O₃, and by NO.OH upon guanin. White amorphous, slightly soluble in boiling water. Easily soluble in solution of H₃N. Hypoxanthin C₅H₄N₄O, crystallizes in needles, slightly soluble. Its hydrochloride sparingly soluble. It accompanies xanthin. Carnin $C_7H_8N_4O_3$, in meat-extract. Theobromin C. H. N. O., in the seeds of Theobroma Cacao. White, crystalline powder, of bitter taste, slightly soluble, neutral. Forms salts with acids. From its solution in H₃N, silver nitrate precipitates C₂H₂AgN₄O₂, which, by heating to 100° C. with CH, I, is changed into: their or methyl-theobromin C₂H₂(CH₃)N₄O₂. In ten and coffee; in the leaves of *llex para*quayensis, and in Guarana, the dried pulp of the trust of Paullinia sorbilis. In silken needles as Call 10 N 4O 2, OH 2, soluble in water and alcohol. Melts at 225° C., and sublimes. Boiled with baryta-water + OH, = theidin C,H,,N,O + CO,. By the

action of Cl or of nitric acid, methylamin and eyanogen chloride are evolved, and AMALIC ACID (TETRA-METHYL ALLOX-

ANTIN) Co(CH3), N,O, is obtained.

Alkaloids of opium. Opium, the inspissated juice of the half-ripe capsules of Papaver somniferum, contains various bases united with sulphurie and meconie acids. By digestion of the opium with warm water, and filtration, we remove narcotin principally, with some resinous matters, &c., and obtain morphin, codein, thebain, papaverin, narcotin and narcein in solution as meconates and sulphates, together with meconin C₁₀H₁₀O₄ and extractive matters. Opium acts as a scalative, and in larger doses as a narcotic poison. On addition of calcium chloride to the aqueous solution, calcium meconate is thrown down, and hydrochlorides of the alkaloids are found in solution.

N.B. MECONIC ACID $C_4HO(COOH)_3$, $OH_2 = C_7H_4O_7$, OH_2 or Oxychelidonic acid (chelidonic acid $C_7H_4O_6$, in Chelidonium majus, together with Aconitic acid $C_6H_6O_6$ in Chelidonium as also in Aconitum napellus) in mica-like plates, easily soluble in boiling water, gives a deep-red color to ferrie salts, not bleached by Cl_2Hg . Easily separated from calcium meconate by ClH. Triatomic, tribasic. Soluble meconates are precipitated by lead

acetate.

Morphin C₁₇H₁₉NO₃,OH₂, in small, brilliant prisms, soluble in 1000 parts of cold water; alkaline to test-paper and of bitter taste. Soluble in 30 parts of boiling alcohol, and easily in dilute acids: insoluble in chloroform and in ether. Soluble in excess of KOH. Precipitated from solutions of its salts by KOH, by H₃N and by CO(ONa)₂. Melts to dark-red fluid, and burns with sooty flame, leaving a little charcoal which easily burns away. Neutral ferric ehloride strikes a blno color. With nitrie acid, an orange color, very characteristic. Liberates I from IO3H, which is dissolved with amethystine color by chloroform or carbonic sulphide, and colors starch blue. From MORPHIN HYDROCHLORIDE $C_{17}H_{19}NO_3$, ClH, 3OH₂, morphin may be precipitated by H_3N . Solution of iodine precipitates $C_{17}H_{19}NO_3I_4$. [Apomorphin $C_{17}H_{17}NO_2$, by heating morphin in an hermetically-scaled tube with 2ClH. Is an emetic. Is soluble in other and in chloroform.] Codein or methyl-morphin $C_{17}H_{18}(CH_3)NO_3, OH_2 = C_{18}H_{21}NO_3, OH_2$. Large rhombic prisms, which melt at 120° C. With soda-lime yields methyl-amin, and trimethylamin. Heated with strong ClH at 145° C., into methyl chloride and apomorphin. Tertiary monamine. From its greater solubility, co tein hydrochloride remains in solution after morphin hydrochloride has crystallized out. Thebain C₁₉H₂₁NO₃ in silvery scales, insoluble in water, KOH and in H3N. Present in very small quantity. Produces tetanns. Papaverin C201121NO1, in minute crystals. Liko

Cryptopin, gives with SO_4H_2 a deep-blue color. Narcotin $C_{22}H_{23}NO_7 = C_{19}H_{14}(CH_3)_3NO_7$, in small, colorless prisms, is obtained from the *marc* or insoluble portion by boiling with dilute acetic acid, and precipitation by NH_3 . Soluble in 128 parts of boiling alcohol and 19 of boiling ether. Heated with KOH, yields H_3N and CH_3H_2N , as well as $(CH_3)_2HN$ and $(CH_3)_3N$. Treated with $_3IH = _3CH_3I + nornarcotin$ $C_{19}H_{17}NO_7$, or three molecules of methyl iodide for one of the new base.

Alkaloids of cinchona. Cinchonin $C_{20}H_{24}N_2O$, in transparent, four-sided prisms, very little soluble in water, yet alkaline to test-paper. Soluble in 30 parts of boiling alcohol; nearly insoluble in ether. A powerful base; produces powerful right-handed rotation. In pale bark, or Cinchona Condaminea. $(C_{20}H_{24}N_2O)_2SO_4H_{2,2}OH_2$, in lustrous crystals, fairly soluble. Cinchonicin and Cinchonidin are isomerie; the first is feebly right-handed, the latter strongly left-handed as to polarized

rays.

Quinin $C_{20}H_{24}N_2O_{23}OH_2$ in minute silken needles, more soluble in water, intensely bitter and alkaline; deviates the plane of polarization to the left. A valuable febrifuge. Very soluble in ether, and gives a green color with Chlorine-water and Ammonia. Abundant in yellow Cinehona bark, Cinchona calisaya. $(C_{20}H_{24}N_2O_2)_2$, SO_4H_{24} , raq., requires 800 parts of cold water for solution. Solution has a blue fluorescence. Quinidin is isomeric, but produces powerful right-handed rotation. Quinicin $C_{20}H_{24}N_2O_2$, is also isomeric, and like cinchonicin is produced by heat respectively from quinidin and cinchonidin. N.B. These alkaloids are contained as Kinates chiefly. The so-called Kinic acid $C_6H_7(OH)_4COOH$, in colorless prisms. Easily obtained from Calcium Kinate $(C_7H_{14}O_6)_2C_{34}$, reaq., by means of oxalic acid. By digesting the ground bark in dilute sulphuric acid, and precipitation of the bases by lime or magnesia.

Alkaloids of strychnos. In the seeds of Strychnos nux-vomica, and in Strychnos Ignatius, STRYCHNIN and BRUCIN are found. The expressed seeds are exhausted by dilute sulphuric acid, and the bases precipitated by ealcium hydroxide: brucin is removed by washing with cold alcohol. Strychnin C₂₁H₂₂N₂O₂, in colorless rhombic prisms, almost insoluble in water, and yet intensely bitter, and alkaline. Almost insoluble in other and absolute alcohol, but very soluble in ordinary spirit of wine and in chloroform. A fearml poison. With PbO₂ and also with MnO₂ and SO₄H₂, gives beautiful purple reaction, turning to brown. Also with K₂Cr₂O₇ and SO₄H₂. Potassium sulphocyanide precipitates sulphocyanide of strychnin. Brucin C₂₂H₂₆N₂O₄, in efflorescent prisms, or in tables with 4 aq. Easily soluble in alcohol, but not in ether. Red with SO₄H₂, and gives a violet precipitate when SnCl₂ is added to the red solution. Orange

color with NO₂.OH, for which it is also a test. Brucea antidysenterica only contains bruein. Less poisonous than strychnin.

Other alkaloids. Atropin C₁₇H₂₃NO₃. in Atropa Belladonna, and in Datura Stramonium. Thin needles, of bitter taste, very poisonous. Unchanged in the urine. Easily soluble in alcohol, but little in water and ether. Produces dilatation of the pupil of the eye. By heating with (OH)₂B₁ or with ClH, by assimilation of OH, into TROPIC ACID C, H10O3 and tropin C, H15NO. Veratrin C₃₀H₅₀N₂O₈, in seeds of Veratrium Sabadilla. White powder, of sharp burning taste, occasioning sneezing. Very poisonous. Nearly in soluble, and yet alkaline. Jervin C₃₀H₄₆N₂O₃, in the root of Veratrum album. [Piperin C₁₇H₁₉NO₃, in four-sided prisms, insoluble in water; easily soluble in alcohol and ether. From seeds of Piper niger. Heated with soda-lime it yields PIPERIDIN C, H, HN, a secondary amine. Sinapin C₁₆H₂₃NO₅, in seed of Sinapis alba, as thioeyanide, soluble in aleohol. By boiling with alkalies $(+2OH_2) = \text{cholin } C_3H_{15}NO_{23}$ and SINAPIC ACID C11H12O2. Hyoscyamin C15H23NO3, in Hyoscyamus niger. Berberin C20H17NO, in the root of Berberis vulgaris. With 5 OH2 in yellow needles. Physostigmin C15H21N3O2, in the Calabar bean. In laminæ soluble in alcohol and ether. A fearful poison. Oceasions contraction of the pupil. Curarin C₁₀H₁₅N. Lycin C₅H₁₁NO₃, in the leaves of Lycium barbarum. Harmalin C₁₃H₁₄N₂O and Harmin C₁₃H₁₂N₂O are in the seeds of Peganum harmala. Colchicin C₁,H₁₉NO₃, in the seeds of Colchicam autumnale. Cocain $C_{17}H_{19}IVO_3$, in coea-leaves. Corydalin $C_{18}H_{19}NO_4$. Chelidonin $C_{10}H_{17}NO_4$, in the roots of Chelidonium majus. Emetin $C_{30}H_{44}N_2O_8$, in Radix Ipecacuanhæ. Solanin C₄₃H₆₉NO₁₆ in the sprouts of Solanum tuberosum. 1

Gelatiginous principles including bone, teeth, hair, nails, &c. Gelatin and Chondrin are not ready-formed, but result from the action of boiling water upon the gelatigenous or ehondrin-producing tissues.

			Gelatin.		Chondrin.
Carbon				50.0	49.1
Hydrogen				6.6	7.1
Nitrogen				18.3	14.4
Oxygen				25.1	29.4
				100.0	0.001

Gelatin swells up in cold water, and dissolves on boiling to a viscid liquid, which solidifies to a jelly on eooling. "Size" from pareliment, "glue" from bones, and "isinglass" from the floating bladder of sturgeous, are more or less pure gelatin. Insoluble in alcohol and ether, and is precipitated also by $\mathrm{Cl_2Hg}$, $(\mathrm{NO_2})_2\mathrm{O_2Hg}$, and $(\mathrm{NO_2})_2\mathrm{O_2Hg}$. Tannin $\mathrm{Cl_4H_{10}O_9}$ (p. 145),

precipitates it as TANNO-GELATIN, and the tissues which yield gelatin, unite directly with tannin to "leather." Boiled with sulphuric acid or with alkalies, gelatin yields both LEUCIN C.H. NO, or AMIDO-CAPROIC ACID C.H. (H.N)(COOH) and GLYCOCIN C2H5NO2 (Or ANIDO-ACETIC ACID CH2(H2N)(COOH). Leucin crystallizes in lustrous scales, but little soluble in water. It unites with acids and bases. Heated with (OH), Ba = C₅H₁₁.H₂N+CO.O₅Ba. Chondrin, from the ribs and joints, is precipitated from its solutions by acetic acid, alum, lead acetate and other metallic salts, and not by mercuric chloride. sulphuric acid, only Levein. Boiled with ClH, gives Glucose .-Sericin C₁₅H₂₅N₅O₈. Soluble in boiling water, and solidifies on cooling to a jelly. Is precipitated by Cy6FeK4, and by various metallic salts. Boiling with sulphuric acid, sericin affords besides LEUCIN CaH13NO, and TYROSIN CaH11NO, serin or amido-glyceric acid CH2.H2N.CHOH.COOH (hard crystals changed by NO.OH into GLYCERIC ACID C3H6O4 or DIOXY-PROPIONIC acid.)—Fibroin C₁₅H₂₃N₃O₆, constitutes 66 per cent. of silk. Insoluble in hot water, in alcohol and ether. Boiled with sulphurie acid, gives

lenein, tyrosin and glycoein.

Albuminoids or proteids. Approximate formula CzeHueNusOceS. They also contain phosphates. Boiled with ClH. and CloSn, they are resolved into H₃N, C₆H₁₃NO₂, C₉H₁₁NO₃, ASPARTIC ACID and GLUTAMIC ACID C3H5.H2N(COOH)2. They are precipitated by mineral acids; by CycFcK, with a little acetic acid; by acetic acid; by Millon's reagent (mercuric nitrate), a deposit, and a solution which turns red. They also rotate the plane of polarization to the right. Class I. ALBUMINS: soluble in water. a. Ser-albumin, yellow, elastic, transparent. soluble, and precipitated by alcohol, which slowly changes it into coagulated albumin. Not precipitated by very dilute acids in small quantities. Immediately by strong acids, especially nitrie acid, in which it is easily soluble. Concentrated NO OH produces a bright orange color. Aqueous solution coagulated by boiling; albumins. Not coagulated: Peptones. All albuminoids changed into Peptones by gastric juice. b. OVALBUMIN, gradually gives a precipitate when shaken with ether, and is nearly insoluble in nitric acid. (The yolk of an egg contains albumin and casein.) c. Vegetalbumin resembles ovalbumin. Class II, GLOBULINS: insoluble in water. Insoluble in water, but soluble in 1 per cent. solution of ClNa or other neutral salts. a. Myosin, insoluble in water, but soluble in very dilute ClH, rapidly passing into acid-albumin. It is also congulated by alcohol. Occurs in the protoplasma, or contractile muscular substance causing rigor mortis. \(\beta\). Globulin, Suspended in water, and heated to 70° C., it becomes coagulate and insoluble. By dilute acids into acid-albumin. In dilute alkalics, soluble as

albuminate. Is precipitated from its saline solution by CO₂, and is prepared from diluted blood-scrum by a stream of CO₂. Globulin also in aqueous humour, in the juice of the cornea, &c. Globulin from blood-scrum is FIBRINO-PLASTIC. y. Fibrinogen is more difficult to precipitate by CO, than globulin, more flaky, and more easily precipitated by alcohol-ether. It is moreover FIBRINGENOUS, producing fibrin when mixed with fibrino-plastic globulin. Prepared from pericardial fluid, or hydrocele fluid, or any other, capable of producing a clot with blood-scrum. Class III. DERIVED ALBUMINS. Insoluble in water and in dilute solutions (1 per cent.) of sodium chloride: soluble in dilute acids and alkalies. A. ACID ALBUMIN, All the globalins of Class II. are soluble in dilute acids, and thus converted into acid albumin, and the precipitate on neutralization is no more soluble in neutral salines. And so, if dilute CIH or CH₃COOH, be added to ser- or ov-albumin, no congulation takes place on heating to 70° C. or above, but rotation to the left is increased: on neutralization, a white, gelatinous precipitate is occasioned, and soluble albumin becomes insoluble in water, as in hot alcohol. Suspended in water and heated to 70° C., it enters into the coagulated state. B. Alkali-albumin or albuminate. Casein. Alkalics similarly prevent coagulation; on neutralization the albumin is similarly precipitated. Hot alcohol re-dissolves alkali-albumin. Casein, from milk, has similar properties: it is coagulated by infusion of rennet. Class IV. FIBRIN. Insoluble in water and in dilute (1 per cent.) hydrogen chloride, except when heated to 60° C. Fibrin is filamentaceous, and elastic, insoluble in water. but soluble in solution of saltpetre at 40° C. The formation of fibrin due to contact of fibrinoplastic with fibrinogenous substances, which combine. Glutin consists mainly of vegetable fibrin and glutin. Class V. Coagulated proteid. Insoluble in dilute, as well as in strong acids: soluble in gastric juice. Produced when neutral solutions of albumin, syntonin, fibrin, myosin, &c., are boiled or precipitated by alcohol. Ovalbumin is also coagulated by ether, and by strong ClH. Casein and albuminates, when precipitated from neutral solutions, pass into coagulated albumin by heat: and they are changed back by caustic potash into albuminates. Class VI. Peptones. All albuminoids changed into peptones by the gastric juice: they are found in the stomach and small intestines. Easily soluble in water, and insoluble in alcohol and other. Not precipitated by acids nor by potassium ferrocyanide, but by Cl., Hg and lead acctate with ammonia.

Bones when dried at 100° C. consist of about one-third of organic matter; the remaining two-thirds being composed chiefly of calcium ortho-phosphate, with calcium carbonate and magnesium phosphate. By boiling in a Papin's digester at 150° C.

the gelatin is dissolved, and the earthy matters are left. The teeth are similar, but the portion which projects over the guins is cucased with a compact hard crust, known as the enamel, and which contains but a very small proportion of animal matter.

Blood is the source of all nutriment and all secretions. Average sp gr. of human blood is from 1.052 to 1.057, varying in the proportion of the red corpuscles. The SERUM is more uniform, between 1.027 and 1.029; alkaline, straw-colored. highly albuminous. Heated to 76°. 7 C., it coagulates to a semitransparent jelly owing to the presence of 7.78 per cent. of albumin. The solid CRUOR or CRASSAMENTUM begins to separate from three to five minutes after the blood has been drawn, and is traced to the action of fibrino-plastic and fibrinogenous bodies; by strong agitation no coagulation, as the fibrin separates in coherent filaments. The blood-discs or red blood-corpuscles consist in chief part of hæmeglobin, or hæmatocrystallin. Usually amorphous, but crystalline from cats, dogs, rats, mice, and many fish. A brick-red powder, soluble in water, and precipitated by alcohol: its aqueous solution exhibits in its spectrum two absorption-bands situated between the Fraunhofer lines D and E. The solution containing 0 has a deep-red color and exhibits the absorption-bands; free from 0 is dark-purple. Oxygenated hæmoglobulin is resolved by dilute acids or alkalies into two proteids, fatty acids, and hæmatin C34H34FeN4O5, a dark-blue powder when dry, containing 9 per cent. of iron. When blood is warmed with strong acetic acid, and solution of ClNa, a substance called hæmin, separates in yellowish-red, microscopic, rhomboids: a test for blood.

Brains. Besides 80 per cent. of water, and 7 per cent. of albumin, the brain contains (in addition to small quantities of kreatin, lactic acid, uric acid, inosite, &c.) fats, cholesterin, cerebrin and lecithin. Cerebrin C₁₇H₃₃NO₃ is a tasteless substance, insoluble in cold other. It swells up when boiled with water. Lecithin C₄₂H₈₄NPO₉, occurs also in yolk of eggs, blood-corpuseles, &c. It is a waxy substance, soluble in alcohol and other; swells up with water, forming an opalescent solution. It units with basyls and radicles. Forms (C₄₂H₃NPO₅Cl)₂. Cl₄Pt By boiling with acids, lecithin into: Cholin C₅H₁₅NO₂,

and GLYCERO-PHOSPHORIC, PALMITIC and OLEIC ACIDS.

Bile. A greenish viscid liquid, which darkens on exposure to air. Alkaline, of disagreeable odor, freely miscible with water, and of bitter taste. Evaporated at 100° C., and treated with alcohol, a thick jelly of mucus is left. The alcoholic solution contains coloring matter and cholesterin C₂₆H₄₃OH (p. 131). The bile-pigments are: a. bilirubin C₁₆H₁₈N₂O₃, the chief coloring matter, forming dark-red prisms, insoluble in

water, and sparingly soluble in alcohol and ether. Easily soluble in CHCl₃ and in S₂C. Soluble in hydroxides, with yellowish-red color; when shaken with air, biliverdin C₁₆H₂₀N₂O₅, of green color, precipitates. b. Bilifuscin C₁₆H₂₀N₂O₄ is darkgreen, soluble in alcohol, but insoluble in chloroforin and in water. With nitric acid, all the pigments give a green color, changing to blue, violet, red and yellow. A test. Besides cholin C3H15NO2 (which has the composition of tri-methyl ethene hydrinanimonium hydroxide C2H4.OH.(CH3)3N.OH), the bile contains two peculiar acids. 1. Glycocholic acid C26H43NO6, slender needles, sparingly soluble in water, easily in alcohol. In the bile, as GLYCOCHOLATE OF SODIUM C26H42NO5ONa. addition of sugar and SO2(OH)2, a purple-red color (Pettenkofer's test). By boiling with alkalies (+ OH2) into GLYCOCIN CH₂(H₂N)COOH, and cholic acid C₂₄H₄₀O₅: boiled with acids, first into glycocin and cholic acid, and the latter then into dyslysin $C_{24}H_{36}O_3$. 2. Taurocholic acid $C_{26}H_{45}NSO_7$, also in slender needles, easily soluble in water and alcohol. By boiling with water $(+ \, \mathrm{OH_2})$, into cholic acid $\mathrm{C_{24}H_{40}O_3}$, and Taurin C2H4(H2N)SO3H, p. 97. In the bile as TAUROCHOLATE OF SODIUM. The bile of pigs contains sodium salts of hyoglycocholic acid $C_{27}H_{43}NO_5$ and hyotaurocholic acid $C_{27}H_{45}NSO_6$. (Hyocholic acid $C_{25}H_{40}O_{44}$) Goose-bile contains chenotaurocholic acid $C_{29}H_{49}NSO_6$. (Chenocholic acid $C_{27}H_{44}O_4$.) Oriental bezoarstones contain ellagic acid $C_{14}H_8O_9$ and lithofellic acid C20 H36O4: the latter gives with sucrose and SO2(OH)2 a purple

Chyle is an opaleseent fluid of a yellowish-white, or pale reddish color. Feebly alkaline, more or less milky from suspended fat globules, and deposits, when boiled, a few albuminous flocculi. Resembles blood, but is far more dilute. Fibrin is greatest when the chyle taken from fasting animals. Lymph is a yellowish or colorless fluid, also of faint alkaline reaction. Like blood and chyle it contains fibrin. The albumin in it varies from 0.4 to 6.0 per cent., and of fibrin from 0.3 to 0.5 per cent. in human beings. Milk, as seen under the microscope, forms a transparent fluid, containing innumerable transparent oily globules; these globules are contained in a thin membrane which is not visible until the milk is treated with dilute acetic acid. Albumin is only present in colostrum, or the milk produced after birth. The quantity of salts in cow's milk amounts to about 0.73 per cent.; the phosphates are the most important. Cow's milk varies in sp. gr. from 1030 to 1040. It contains about 12.5 per cent. of total solids: FAT 3.25; LACTOSE and soluble salts 5.20; CASEIN and insoluble salts

Among the liquids concerned in digestion (besides bile) we

notice: Saliva. An opalescent, viscid liquid, which froths on agitation. The solids vary from 0.4 to 0.84. In addition to epithelial particles, and to the muchs derived from the mouth, the saliva coutaius ptyalin which resembles sodium albuminate. It constitutes one-third of the soluble solids of the saliva, and converts starch into dextrin and dextrose. Further, the saliva is faintly alkaline. Besides carbonates and lactates of potassium aud sodium, it contains sulphocyanide of potassinm, carbonate and phosphate of calcium, the two last, together with salivary mucus, constituting the tartar of teeth. The gastric juice effects the digestion of the albuminoid constituents of food. It is a clear colorless liquid, of peculiar odor; very acid after ingestion of food. Very powerful antiseptic. Does uot become turbid when boiled. The acid consists of lactic and hydrochloric acids, with traces of butyric and propionic. Besides certain salts, it contains Pepsin, an albaminoid body, soluble in water, but insoluble in alcohol or in ether. When boiled, pepsin loses its power of effecting digestion: its aqueous solution is precipitated by ClaHg, but not by CyaFeK, in acetic acid solutions. Dried pepsin with 20 to 50 per cent. of starch, is an article of commerce. The Pancreatic fluid, somewhat resembles saliva. It aids in the assimilation of fats. Sp. gr. 1,008. Contains about 10 per cent. of solids, among which Leucin $C_3H_{10}.H_2N.COOH$, Xanthin $C_3H_4N_4O_2$, Guanin $C_5H_5N_5O$ and inosite $C_6H_{12}O_6$. Further it contains albumin, and becomes coagulated when heated. Mucus. A tough, viscid secretion, in which epithelial particles can be traced in different stages of disintegration. It swells up in, but is not dissolved by, water: MUCIN gives the glairy consistence to the mass, and is turned yellow by uitric acid, not precipitated by Cl. Hg, but eoagulated by alcohol.

The Urine. From arterial blood by the kidneys. Average sp. gr. 1.02. The quantity passed by an adult varies from 40 to 50 oz. per day. Amber-colored, of slight acid reaction, and peculiar odor. It soon begins to putrefy, and becomes alkaline from the couversion of UREA CON, H, + 2OH, into AMMONIUM CARBONATE: the mueus of the bladder acting as a ferment. Besides WATER 95.680 per cent., and UREA CON. H4, 1.420 per cent., the urino contains MUCUS 0.016, URIC ACID C.H.N.O., 0.037 per cent., ALCOHOLIC EXTRACT 1.253, AQUEOUS EXTRACT 0.250, SODIUM CHLORIDE 0.722, PHOSPHATES, SULPHATES, &c., 0.613 per cent. The urine of herbivora is rich in hippuric ACID CH2.NH.C2H5O.COOH. The coloring matters of the urine. UROCHROME and UROMELANIN C36H43N7O10. The urine is the chief outlet of the effete nitrogenized tissues. Lehmann secreted 821 graius of urea, and 21.6 grains of uric acid, per 24 hours, on an animal diet; on a vegetable diet 348 grains of urea, and 15.4 grains of uric acid. Sulphates increase greatly in the urine with animal food. All salts of potassium, sodium and ammonium with vegetable acids, taken as such, are voided as earbonates. In certain diseases, albumin is found in the urine. In diabetes, the urine contains much dextrose. Chief calculi are: I. Uric acid. 2. Ammonium urate. The deposit so common in urine, of a pink color, is urate of ammonium. 3. Calcium oxalate. "Mulberry calculns." 4. Calcium orthophosphate: infusible. 5. Ammonium magnesium phosphate. Triple phosphate." "Fusible calculus" is a mixture of 4 and 5. 6. Xanthin $C_5H_4N_4O_2$; very rare. 7. Cystin $C_3H_6NSO_2$.—An important biliary calculus consists mainly of cholesterin $C_{26}H_{43}OH$.

The solid excrements or fæces consist of about 75 per eent. of water; the rest, of biliary matters and alimentary débris According to Liebig, about 5½ ounces are excreted in 24 hour; by a healthy adult. The odor is the more offensive as the quantity of bile diminishes. Marcet has discovered EXCRETIN

C₇₈H₁₅₆SO₂.

Pus is a thick, opake, yellowish fluid, which, under the microscope is seen to consist of a transparent liquid, in which a large number of corpuseles float. It is feebly alkaline, and holds a considerable quantity of albumin in solution; LEUCIN C₅H₁₀(H₂N)COOH, is also often present, and has been already mentioned at pp. 126 and 130. [Lencin is further formed by the decomposition of gelatin, wool and horn, &c., during putrefaction. Indeed, it was first discovered in putrid cheese. The crystals melt at 100°C., and sublime. Nitrous acid changes leucin into LEUCIC ACID C₆H₁₂O₃. It is produced artificially from BROMO-CAPROIC ACID by ammonia, and by digesting VALERAL-AMMONIA with cyanide of hydrogen and chlorido of hydrogen. Thus: $C_5H_{10}O.H_3N + CNH + OH_2 + CHH = H_4NCI + C_5H_{10}.H_2N.COOH.$ The pus-globules contain both fat and CHOLESTERIN C26H43OH, the latter having the composition of a monatomic alcohol. It is a lustrous, fat-like substance, soluble in boiling alcohol, in other and in chloroform. It melts at 137° C., and sublimes at 200° C. It is the chief constituent of biliary calculi (p. 128). PYIN is the name of the albuminoid substance found in pus; it is soluble in water, but precipitated by acetic acid as well as by alum. The saline constituents exceed 12 per cent. of the total dry matter.

THE END.

LONDON:

PRINTED BY WILLIAM CLOWES AND SONS, STAMFORD STREET AND CHARING CROSS.

- A Handy-Book of Forensic Medicine and Toxi-COLOGY. By W. BATHURST WOODMAN, M.D., F.R.C.P., and C. MEYMOTT TIDY, M.D., F.C.S. With 8 Lithographic Plates and 116 Engravings. 8vo. 31s. 6d.
- Qualitative Analysis. By C. Remigius Fresenius. Edited by Arthur Vacher. Ninth Edition, with Coloured Plate of Spectra and 47 Engravings. 8vo. 12s. 6d.

By th: same Author.

- Quantitative Analysis. Edited by ARTHUR VACHER. Seventh Edition. Vol. I. With 106 Engravings. 8vo. 15s.
- A Primer of Chemistry, including Analysis. By ARTHUR VACHER. 18mo. 1s.
- Practical Chemistry and Qualitative Inorganic ANALYSIS. By FRANK CLOWES, D.Sc. Lond., F.C.S. Lond. and Berlin. Second Edition. With 47 Engravings. Crown 8vo. 7s. 6d.
- Practical Chemistry, including Analysis. By John E. Bowman and C. L. Bloxam. Sixth Edition. With 98 Engravings. Feap. 8vo. 6s. 6d.
- The First Step in Chemistry: a New Method for Teaching the Elements of the Science. By ROBERT GALLOWAY. Fourth Edition, with Engravings. Fcap. 8vo. 6s. 6d.

By the same Author.

- A Manual of Qualitative Analysis. Fifth Edition, with Engravings. Post 8vo. 8s. 6d.
- Handbook of Chemical Technology. By Rudolf Wagner, Ph.D. Translated and Edited from the Eighth German Edition, with Extensive Additions by William Crookes, F.R.S. With 336 Engravings. 8vo. 25s.
- How to Teach Chemistry: Hints to Science Teachers and Students. Six Lectures by Edward Frankland, D.C.L., F.R.S. Summarised and Edited by George Chaloner, F.C.S. With 47 Engravings. Crown 8vo. 3s. 6d.
- A Manual of Photographic Manipulation. By LAKE PRICE. Second Edition, with numerous Engravings. Crown 8vo. 6s. 6d.

- A Manual of Photography. By George Dawson, M.A., Ph.D. Eighth Edition, with Engravings. Fcap. 8vo. 5s. 6d.
- The Microscope and its Revelations. By W. B. Carpenter, M.D., F.R.S. Fifth Edition, with more than 500 Engravings. Crown 8vo. 15s.
- The Microscopist: a Manual of Microscopy and Compendium of the Microscopic Sciences, Micro-Mineralogy, Micro-Chemistry, Biology, Histology, and Pathological Histology. By J. H. WYTHE, A.M., M.D. Third Edition, with 205 Engravings. 8vo. 18s.
- A Manual of the Anatomy of Invertebrated ANIMALS. By Professor Huxley, LL.D., F.R.S. With 158 Engravings. Fcap. 8vo. 16s.
- Dental Anatomy, Human and Comparative:

 A Manual. By CHARLES S. TOMES, M.A., M.R.C.S. With 179
 Engravings. Crown 8vo. 10s. 6d.
- Atlas of Topographical Anatomy, after Plane Sections of Frozen Bodies. By WILHELM BRAUNE. Translated by EDWARD BELLAMY, F.R.C.S. With 34 Photo-Lithographic Plates and 46 Woodcuts. Large Imp. 8vo. 40s.
- Histology and Histo-Chemistry of Man: a
 Treatise on the Elements of Composition and Structure of the
 Human Body. By Heinrich Frey. Translated from the Fourth
 German Edition by Arthur E. J. Barker. And Revised by the
 Author. Svo. With 608 Engravings. 21s.
- A Manual of Animal Physiology. With Appendix of Examination Questions. By John Shea, M.D., B.A. Lond. With numerous Engravings. Fcap. 8vo. 5s. 6d.
- Manual of Comparative Anatomy and Phy-SIOLOGY. By S. Messenger Bradley, F.R.C.S. Third Edition, with 61 Engravings. Post 8vo. 6s. 6d.
- An Introduction to Physical Measurements.
 With Appendices on Absolute Electrical Measurement, &c. By
 Dr. F. Kohlerausch. Translated from the Second German Edition
 by T. H. Waller, B.A., B.Sc., and H. R. Procter, F.C.S. With
 Engravings. 8vo. 12s.

The Pocket Formulary and Synopsis of the BRITISH and FOREIGN PHARMACOPŒIAS: Comprising Standard and approved Formulæ for the Preparations and Compounds employed in Medical Practice. By HENRY BEASLEY. Tenth Edition. 18mo. 6s. 6d.

By the same Author,

The Druggist's General Receipt-Book: comprising a Copious Veterinary Formulary and Table of Veterinary Materia Medica; Patent and Proprietary Medicines, Druggists' Nostrums, &c.; Perfumery, Skin Cosmetics, Hair Cosmetics, and Teeth Cosmetics; Beverages, Dietetic Articles and Condiments; Trade Chemicals, Miscellaneous Preparations and Compounds used in the Arts, &c.; with useful Memoranda and Tables. Seventh Edition. 18mo. 6s.

Also,

- The Book of Prescriptions: containing 3,107 Prescriptions collected from the Practice of the most eminent Physicians and Surgeons, English and Foreign. With an Index of Diseases and Remedies. Fifth Edition. 18mo. 6s. 6d.
- A Pharmacopæia, including the Outlines of MATERIA MEDICA and THERAPEUTICS, for the Use of Praetitioners and Students of Veterinary Medicine. By RICHARD V. TUSON, F.C.S. Second Edition. Post 8vo. 7s. 6d.
- Pharmaceutical Guide to the First and Second EXAMINATIONS. By JOHN BARKER SMITH. Second Edition. Crown 8vo. 6s. 6d.
- Lectures on Practical Pharmacy. By BARNARD S. PROCTOR, With 43 Engravings. 8vo. 12s.
- A Dictionary of Materia Medica and Thera-PEUTICS. By ADOLPHE WAHLTUCH, M.D. 8vo. 10s. 6d.
- Medical Lexicon: a Dictionary of Medical SCIENCE. Containing a Coneise Explanation of the various Subjects and Terms of Anatomy, Physiology, Pathology, Hygiene, Therapeuties, Pharmacology, Pharmacy, Surgery, Obstetries, Medical Jurisprudence, and Dentistry, Notices of Climate and of Mineral Waters, Formulæ for Officinal, Empirical, and Dictetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonyms. By ROBLEY DUNGLISON, M.D. New Edition. By RICHARD J. DUNGLISON, M.D. Royal 8vo. (1,130 pp.) 28s.

- A Handbook of Hygiene and Sanitary Science. By George Wilson, M.A., M.D. Third Edition. Post 8vo., with Engravings. 10s. 6d.
- Surgical Emergencies, together with the Emergencies attendant on Parturition and the Treatment of Poisoning: a Manual for the use of General Practitioners. By WILLIAM P. SWAIN, F.R.C.S. Second Edition. Post 8vo. With 104 Engravings. 6s. 6d.
- Minor Surgery and Bandaging: a Manual for the Use of House-Surgeons, Dressers, and Junior Practitioners. By Christopher Heath, F.R.C.S. Fifth Edition. Feap. 8vo. With 86 Engravings. 5s. 6d.
- Handbook for Nurses for the Sick. By Zephe-RINA P. VEITCH. Second Edition. Crown 8vo. 3s. 6d.
- The Nurse's Companion: a Manual of General and Monthly Nursing. By Charles J. Cullingworth. Fcap. 8vo. 2s. 6d.
- Lectures on Nursing. By WILLIAM ROBERT SMITH, M.B. Second Edition. With 26 Engravings. Post Svo. 6s.
- The Cottage Hospital: its Origin, Progress, Management, and Work. By HENRY C. BURDETT. With Engravings. Crown 8vo. 7s. 6d.
- Atlas of Skin Diseases: a Series of Illustrations, with Descriptive Text and Notes upon Treatment. By Tilbury Fox, M.D., F.R.C.P. With 72 Coloured Plates. Royal 4to., half morocco. £6 6s.
- Operative Dentistry: a Practical Treatise. By
 JONATHAN TAFT, D.D.S. Third Edition, thoroughly revised.
 With many additions, and 134 Engravings. 8vo. 18s.
- Phthisis: in a Series of Clinical Studies. By Austin Flint, M.D. 8vo. 16s.

By the same Author.

A Manual of Percussion and Auscultation, of the PHYSICAL DIAGNOSIS OF DISEASES of the LUNGS AND HEART, and of THORACIC ANEURISM. Post 8vo. 6s. 6d.

J. & A. CHURCHILL'S MEDICAL CLASS BOOKS.

ANATOMY.

BRAUNE.—An Atlas of Topographical Ana-

tomy, after Plane Sections of Frozen Bodies. By Wilhelm Braune, Professor of Anatomy in the University of Leipzig. Translated by Edward Bellamy, F.R.C.S., and Member of the Board of Examiners; Surgeon to Charing Cross Hospital, and Lecturer on Anatomy in its School. With 34 Photo-lithographic Plates and 46 Woodcuts. Large imp. 8vo, 40s.

FLOWER.—Diagrams of the Nerves of the

Human Body, exhibiting their Origin, Divisions, and Connexions, with their Distribution to the various Regions of the Cutaneous Surface, and to all the Muscles. By William H. Flower, F.R.C.S., F.R.S. Hunterian Professor of Comparative Anatomy, and Conservator of the Museum, Royal College of Surgeons. Third Edition, containing 6 Plates. Royal 4to, 12s.

GODLEE.—An Atlas of Human Anatomy:

illustrating most of the ordinary Dissections; and many not usually practised by the Student. By RICKMAN J. GODLEE, M.S., F.R.C.S., Assistant-Surgeon to University College Hospital, and Senior Demonstrator of Anatomy in University College. With 48 Imp. 4to Coloured Plates, containing 112 Figures, and a Volume of Explanatory Text, with many Engravings, 8vo, £4 14s. 6d.

HEATH.-Practical Anatomy: a Manual of

Dissections. By Christopher Heath, F.R.C.S., Holme Professor of Clinical Surgery in University College and Surgeon to the Hospital, Fifth Edition. With 24 Coloured Plates and 269 Engravings. Crown 8vo, 15s.

ANATOMY—continued.

HOLDEN.—A Manual of the Dissection of

Hnman Body. By Luther Holden, F.R.C.S., Consulting-Surgeon to St. Bartholomew's Hospital. Fourth Edition. Revised by the Anthor and John Langton, F.R.C.S., Assistant Surgeon and Lecturer on Anatomy at St. Bartholomew's Hospital. With Engravings. 8vo, 16s.

By the same Author.

Human Osteology: comprising a Descrip-

tion of the Boncs, with Delineations of the Attachments of the Muscles, the General and Microscopieal Structure of Bone and its Development. Sixth Edition, revised by the Anthor and Alban Boran, F.R.C.S., late Anatomical, now Pathological, Assistant to the Museum of the Royal College of Surgeons. With 61 Lithographic Plates and 89 Engravings. Royal Svo.

[Nearly ready.

ALSO,

Landmarks, Medical and Surgical. Third Edition. Svo, 3s. 6d.

LANCEREAUX.—Atlas of Pathological Ana-

tomy. By Dr. Lancereaux. Translated by W. S. Greenfield, M.D., Professor of Pathology in the University of Edinburgh. With 70 Coloured Plates. Imperial Svo. £5 5s.

MORRIS.—The Anatomy of the Joints of Man.

By Henry Morris, M.A., F.R.C.S., Surgeon to, and Lecturer on Anatomy and Practical Surgery at, the Middlesex Hospital. With 44 Plates (19 Colonred) and Engravings. Svo, 16s.

The Anatomical Remembrancer; or, Complete Pocket Anatomist. Eighth Edition. 32mo, 3s. 6d.

WAGSTAFFE.—The Student's Guide to Human

Osteology. By WM. WARWICK WAGSTAFFE, F.R.C.S., Assistant-Surgeon to, and Lecturer on Anatomy at, St. Thomas's Hospital. With 23 Plates and 66 Engravings. Fcap. 8vo, 10s. 6d.

ANATOMY—continued.

WILSON — BUCHANAN — CLARK. — Wilson's

Anatomist's Vade-Mecum: a System of Human Anatomy. Tenth Edition, by George Buchanan, Professor of Clinical Surgery in the University of Glasgow, and Henry E. Clark, M.R.C.S., Lecturer on Anatomy in the Glasgow Royal Infirmary School of Medicine. With 450 Engravings, including 26 Coloured Plates. Crown 8vo, 18s.

BOTANY.

BENTLEY.—A Manual of Botany. By Robert

Bentley, F.L.S., Professor of Botany in King's College and to the Pharmaceutical Society. With nearly 1200 Engravings. Fourth Edition. Crown 8vo. [Nearly ready.

BENTLEY AND TRIMEN .- Medicinal Plants:

being descriptions, with original Figures, of the Principal Plants employed in Medicine, and an account of their Properties and Uses. By ROBERT BENTLEY, F.L.S., and HENRY TRIMEN, M.B., F.L.S. In 4 Vols., large 8vo, with 306 Coloured Plates, bound in half morocco, gilt edges, £11 11s.

CHEMISTRY.

BERNAYS .- Notes for Students in Chemistry;

being a Syllabus of Chemistry compiled mainly from the Manuals of Fownes-Watts, Miller, Wurz, and Schorlemmer. By Albert J. Beinays, Ph.D., Professor of Chemistry at St. Thomas's Hospital. Sixth Edition. Fcap. 8vo, 3s. 6d.

By the same Author.

Skeleton Notes on Analytical Chemistry, for Students in Medicine. Fcap. Svo, 2s. 6d.

BOWMAN AND BLONAM.—Practical Chemistry,

including Analysis. By John E. Bowman, formerly Professor of Practical Chemistry in King's College, and Charles L. Blonam, Professor of Chemistry in King's College. With 98 Engravings. Seventh Edition. Feap. 8vo, 6s. 6d.

CHEMISTRY—continued.

BLOXAM.—Chemistry, Inorganic and Organic; with Experiments. By Charles L. Bloxam, Professor of Chemistry in King's College. Fourth Edition. With nearly 300 Engravings. 8vo, 16s.

By the same Author.

Laboratory Teaching; or, Progressive Exercises in Practical Chemistry. Fourth Edition. With 83 Engravings. Crown 8vo, 5s. 6d.

CLOWES.—Practical Chemistry and Qualitative Inorganic Analysis. An Elementary Treatise, specially adapted for use in the Laboratories of Schools and Colleges, and by Beginners. By Frank Clowes, D.Sc., Senior Science Master at the High School, Newcastle-under-Lyme. Third Edition. With 47 Engravings. Post Svo. 7s. 6d.

FOWNES AND WATTS.—Physical and Inorganic Chemistry. Twelfth Edition. By George Fownes, F.R.S., and Henry Watts, B.A., F.R.S. With 154 Engravings, and Coloured Plate of Spectra. Crown Svo, Ss. 6d.

By the same Authors.

- Chemistry of Carbon Compounds, or Organic Chemistry. Twelfth Edition. With Engravings. Crown Svo, 10s.
- LUFF.—An Introduction to the Study of Chemistry. Specially designed for Medical and Pharmaceutical Students. By A. P. Luff, F.I.C., F.C.S., Lecturer on Chemistry in the Central School of Chemistry and Pharmacy. Crown Syo, 2s. 6d.
- TIDY.—A Handbook of Modern Chemistry, Inorganie and Organic. By C. Meynort Tidy, M.B., Professor of Chemistry and Medical Jurisprudence at the London Hospital. Svo, 16s.
- VACHER.—A Primer of Chemistry, including Analysis. By Anthur Vacher. 18mo. 1s.

CHEMISTRY—continued.

VALENTIN.—Introduction to Inorganic Chemistry. By WILLIAM G. VALENTIN, F.C.S. Third Edition. With 82 Engravings. Svo, 6s. 6d.

By the same Author.

A Course of Qualitative Chemical Analysis.

Fifth Edition by W. R. Hodgkinson, Ph.D. (Würzburg), Demonstrator of Practical Chemistry in the Science Training Schools. With Engravings. 8vo, 7s. 6d.

ALSO,

Chemical Tables for the Lecture-room and Laboratory. In Five large Sheets, 5s. 6d.

CHILDREN, DISEASES OF.

DAY.—A Treatise on the Diseases of Children.
For Practitioners and Students. By WILLIAM H. DAY, M.D., Physician

to the Samaritan Hospital for Women and Children. Crown Svo, 12s. 6d.

- ELLIS.—A Practical Manual of the Diseases of Children. By Edward Ellis, M.D., late Senior Physician to the Victoria Hospital for Sick Children. With a Formulary. Fourth Edition. Crown 8vo.

 [Nearly ready.]
- SMITH.—Clinical Studies of Disease in Children. By Eustage Smith, M.D., F.R.C.P., Physician to H.M. the King of the Belgians, and to the East London Hospital for Children. Post 8vo, 7s. 6d.

By the same Author.

- On the Wasting Diseases of Infants and Children. Third Edition. Post 8vo, 8s. 6d.
- STEINER.—Compendium of Children's Diseases; a Handbook for Practitioners and Stadents. By Johann Steiner, M.D. Translated by Lawson Tait, F.R.C.S., Surgeon to the Birmingham Hospital for Women, &c., Syo, 12s, 6d.

DENTISTRY.

- SEWILL.—The Student's Guide to Dental Anatomy and Surgery. By Henry E. Sewill, M.R.C.S., L.D.S., late Dental Surgeon to the West London Hospital. With 77 Engravings. Feap. 8vo, 5s. 6d.
- SMITH.—Handbook of Dental Anatomy and Surgery. For the Use of Students and Practitioners. By John Smith, M.D., F.R.S.E., Dental Surgeon to the Royal Infirmary, Edinburgh. Second Edition. Fcap. 8vo, 4s. 6d.
- STOCKEN.—Elements of Dental Materia Medica and Therapeutics, with Pharmacoposia. By James Stocken, L.D.S.R.C.S., late Lecturer on Dental Materia Medica and Therapeutics and Dental Surgeon to the National Dental Hospital. Third Edition. Feap. 870.

 [In the press.]
- TAFT.—A Practical Treatise on Operative

 Dentistry. By Jonathan Taft, D.D.S., Professor of Operative Surgery
 in the Ohio College of Dental Surgery. Third Edition. With 134
 Engravings. Svo, 18s.
- TOMES (C. S.).—Manual of Dental Anatomy, Human and Comparative. By Charles S. Tomes, M.A., M.R.C.S., Lecturer on Anatomy and Physiology at the Dental Hospital of London. Second Edition. With Engravings. Crown Svo. [In preparation.
- TOMES (J. and C. S.).—A Manual of Dental Surgery. By John Tomes, M.R.C.S., F.R.S., and Charles S. Tomes, M.A., M.R.C.S. Second Edition. With 262 Engravings. Fcap. 8vo. 14s.

EAR, DISEASES OF.

BURNETT.—The Ear: its Anatomy, Physiology, and Diseases. A Practical Treatise for the Use of Medical Students and Practitioners. By Charles H. Burnett, M.D., Aural Surgeon to the Presbyterian Hospital, Philadelphia. With 87 Engravings. 8vo, 18s.

EAR, DISEASES OF-continued.

DALBY.—On Diseases and Injuries of the Ear.

By WILLIAM B. DALBY, F.R.C.S., Aural Surgeon to, and Lecturer on Aural Surgery at, St. George's Hospital. Second Edition. With Engravings. Fcap. 8vo, 6s. 6d.

JONES.-A Practical Treatise on Aural Sur-

gery. By H. Machaughton Jones, M.D., Professor of the Queen's University in Ireland, Surgeon to the Cork Ophthalmic and Aural Hospital. With 46 Engravings. Crown Svo, 5s.

By the same Author.

Atlas of the Diseases of the Membrana

Tympani. In Coloured Plates, containing 59 Figures. With Explanatory Text. Crown 4to, 21s.

FORENSIC MEDICINE.

OGSTON.-Lectures on Medical Jurisprudence.

By Francis Ogston, M.D., Professor of Medical Jurisprudence and Medical Logic in the University of Aberdeen. Edited by Francis Ogston, Jun., M.D., Assistant to the Professor of Medical Jurisprudence and Lecturer on Practical Toxicology in the University of Aberdeen. With 12 Plates. Svo. 15s.

TAYLOR.—The Principles and Practice of

Medical Jurisprudence. By ALFRED S. TAYLOR, M.D., F.R.S., late Professor of Medical Jurisprudence to Guy's Hospital. Second Edition. With 189 Engravings. 2 Vols. Svo. 31s. 6d.

By the same Author.

A Manual of Medical Jurisprudence.

Tenth Edition. With 55 Engravings. Crown 8vo. 14s.

ALSO,

On Poisons, in relation to Medical Jurisprudence and Medicine. Third Edition. With 104 Engravings.

Crown Svo, 16s.

WOODMAN AND TIDY.—A Handy-Book of

Forcusic Medicine and Toxicology. By W. BATHURST WOODMAN, M.D., F.R.C.P.; and C. MEYMOTT TIDY, M.B. With 8 Lithographic Plates and 116 Wood Engravings. Syo, 31s. 6d.

HYGIENE.

- PARKES.—A Manual of Practical Hygiene.

 By Edmund A. Parkes, M.D., F.R.S. Fifth Edition by F. De Chaumont,
 M.D., F.R.S., Professor of Military Hygiene in the Army Medical
 School. With 9 Plates and 112 Engravings. Svo, 18s.
- WILSON.—A Handbook of Hygiene and Sanitary Science. By George Wilson, M.A., M.D., Medical Officer of Health for Mid Warwickshire. Fourth Edition. With Engravings. Crown 8vo, 10s. 6d.

MATERIA MEDICA AND THERAPEUTICS.

- BINZ AND SPARKS.—The Elements of Therapeutics: a Clinical Guide to the Action of Medicines. By C. Binz, M.D., Professor of Pharmacology in the University of Bonn. Translated and Edited with Additions, in conformity with the British and American Pharmacopeias. by Edward I. Sparks, M.A., M.B., F.R.C.P. Lond. Crown Svo, 8s. 6d.
- OWEN.—Tables of Materia Medica; comprising the Contents, Doses, Proportional Composition, and Methods of Manufacture of Pharmacopeial Preparations. By Isambard Owen, M.B., M.R.C.P., Lecturer on Materia Medica at St. George's Hospital. Fifth Edition. Crown Svo, 2s. 6d.
- ROYLE AND HARLEY.—A Manual of Materia Medica and Therapeuties. By J. Forbes Royle, M.D., F.R.S., and John Harley, M.D., F.R.C.P., Physician to, and Joint Lecturer on Clinical Medicine at, St. Thomas's Hospital. Sixth Edition. With 139 Engravings Crown 8vo, 15s.
- THOROWGOOD. The Student's Guide to Materia Medica. By JOHN C. THOROWOODD, M.D., F.R.C.P., Lecturer on Materia Medica at the Middlesex Hospital. With Engravings. Fcap. 8vo, 6s. 6d.
- WARING.—A Manual of Practical Therapeutics. By Edward J. Waring, C.B., M.D., F.R.C.P. Third Edition. Feap. Svo, 12s. 6d.

MEDICINE.

BARCLAY .- A Manual of Medical Diagnosis.

By A. Whyte Barclay, M.D., F.R.C.P., Physician to, and Lecturer on Medicine at, St. George's Hospital. Third Edition. Fcap. 8vo, 10s. 6d.

CHARTERIS.—The Student's Guide to the

Practice of Medicine. By MATTHEW CHARTERIS, M.D., Professor of Materia Medica, University of Glasgow; Physician to the Royal Infirmary. With Engravings on Copper and Wood. Third Edition. Fcap. 8vo, 7s.

FENWICK.—The Student's Guide to Medical

Diagnosis. By Samuel Ferwick, M.D., F.R.C.P., Physician to the London Hospital. Fifth Edition. With 111 Engravings. Fcap. 8vo, 7s.

By the same Author.

- The Student's Outlines of Medical Treatment. Second Edition. Feap. 8vo, 7s.
- FLINT.—Clinical Medicine: a Systematic Treatise on the Diagnosis and Treatment of Disease. By Austin Flint, M.D., Professor of the Principles and Practice of Medicine, &c., in Bellevue Hospital Medical College. Svo. 20s.

By the same Author.

A Manual of Percussion and Auscultation; of the Physical Diagnosis of Diseases of the Lungs and Heart, and

of Thoracic Aneurism. Post 8vo, 6s. 6d.

- HALL.—Synopsis of the Diseases of the Larynx, Lungs, and Heart: comprising Dr. Edwards' Tables on the Examination of the Chest. With Alterations and Additions. By F. DE HAVILLAND HALL, M.D., F. R.C.P., Assistant-Physician to the Westminster Hospital. Royal Svo, 2s. 6d.
- SANSOM.--Manual of the Physical Diagnosis of Diseases of the Heart, including the use of the Sphygmograph and Cardiograph. By A. E. Sanson, M.D., F.R.C.P., Assistant-Physician to the London Hospital. Third Edition, with 47 Woodcuts. Fcap. 8vo, 7s. 6d.

MEDICINE—continued.

- WARNER.—Student's Guide to Medical Case-Taking. By Francis Warner, M.D., Assistant-Physician to the London Hospital. Feap. Syo. 5s.
- WHITTAKER.—Students' Primer on the Urine.
 By J. Trans Whittaker, M.D., Clinical Demonstrator at the Royal
 Infirmary, Glasgow. With Illustrations, and 16 Plates etched on
 Copper. Post Svo, 4s. Cd.

MIDWIFERY.

- BARNES.—Lectures on Obstetric Operations, including the Treatment of Hæmorrhage, and forming a Guide to the Management of Difficult Labour. By Robert Barnes, M.D., F.R.C.P., Obstetric Physician to, and Lecturer on Diseases of Women, &c., at St. George's Hospital. Third Edition. With 124 Engravings. Svo. 18s.
- CLAY.—The Complete Handbook of Obstetric
 Surgery; or, Short Rules of Practice in every Emergency, from the
 Simplest to the most formidable Operations connected with the Science
 of Obstetricy. By Charles Clay, M.D., late Senior Surgeon to, and
 Lecturer on Midwifery at, St. Mary's Hospital, Manchester. Third
 Edition. With 91 Engravings. Fcap. Svo, 6s. 6d.
- RAMSBOTHAM.—The Principles and Practice of Obstetric Medicine and Surgery. By Francis H. Ramsbotham, M.D., formerly Obstetric Physician to the London Hospital. Fifth Edition. With 120 Plates, forming one thick handsome volume. Svo, 22s.
- REYNOLDS.—Notes on Midwifery: specially designed to assist the Student in preparing for Examination. By J. J. REYNOLDS, M.R.C.S. Feap. 8ve, 4s.
- ROBERTS.—The Student's Guide to the Practice of Midwifery. By D. LLOYD ROBERTS, M.D., F.R.C.P., Physician to St. Mary's Hospital, Manchester. Second Edition. With 111 Engravings. Feap. 8vo, 7s.

MIDWIFERY—continued.

- SCHROEDER.—A Manual of Midwifery; including the Pathology of Pregnancy and the Puerperal State. By Karl Schroeder, M.D., Professor of Midwifery in the University of Erlangen. Translated by Charles H. Carter, M.D. With Engravings. Svo, 12s. 6d.
- SWAYNE.—Obstetric Aphorisms for the Use of Students commencing Midwifery Practice. By Joseph G. Swayne, M.D., Lecturer on Midwifery at the Bristol School of Medicine. Seventh Edition. With Engravings. Fcap. Svo, 3s. 6d.

MICROSCOPY.

- CARPENTER.—The Microscope and its Revelations. By William B. Carpenter, C.B., M.D., F.R.S. Sixth Edition. With 26 Plates, a Coloured Frontispiece, and more than 500 Engravings. Crown 8vo, 16s.
- MARSH.—Section-Cutting: a Practical Guide to the Preparation and Mounting of Sections for the Microscope, special prominence being given to the subject of Animal Sections. By Dr. Sylvester Marsh. With Engravings. Feap. 8vo, 2s. 6d.
- MARTIN.—A Manual of Microscopic Mounting. By John H. Martin, Member of the Society of Public Analysts, &c. Second Edition. With several Plates and 144 Engravings. Svo, 7s. 6d.

OPHTHALMOLOGY.

- DACCUENET.—A Manual of Ophthalmoscopy for the Use of Students. By Dr. DAGUENET. Translated by C. S. JEAFFRESON, Surgeon to the Newcastle-on-Tyne Eye Infirmary. With Engravings. Feap. 8vo, 5s.
- IIIGGENS.—Hints on Ophthalmic Out-Patient Practice. By Charles Higgens, F.R.C.S., Ophthalmic Assistant-Surgeon to, and Lecturer on Ophthalmology at, Gny's Hospital. Second Edition. Feap. Svo, 3s.

OPHTHALMOLOGY—continued.

JONES.—A Manual of the Principles and Practice of Ophthalmic Medicine and Surgery. By T. WHARTON JONES, F.R.C.S., F.R.S., late Ophthalmic Surgeon and Professor of Ophthalmology to University College Hospital. Third Edition. With 9 Coloured Plates and 173 Engravings. Feap. Svo. 12s. 6d.

- MACNAMARA.—A Manual of the Diseases of the Eye. By CHARLES MACNAMARA, F.R.C.S., Surgeon to Westminster Hospital. Third Edition. With 7 Coloured Plates and 52 Engravings. Fcap. Svo, 12s. 6d.
- NETTLESHIP.—The Student's Guide to Diseases of the Eye. By Edward Nettleship, F.R.C.S., Ophthalmic Surgeon to, and Lecturer on Ophthalmic Surgery at, St. Thomas's Hospital. With 48 Engravings. Fcap. 8vo, 7s. 6d.

PATHOLOGY.

JONES AND SIEVEKING.—A Manual of Pathological Anatomy. By C. Handfield Jones, M.B., F.R.S., and Edward H. Sieveking, M.D., F.R.C.P. Second Edition. Edited, with considerable enlargement, by J. F. Payne, M.B., Assistant-Physician and Lecturer on General Pathology at St. Thomas's Hospital. With 195 Engravings. Crown 8vo, 16s.

- VIRCHOW. Post-Mortem Examinations: a Description and Explanation of the Method of Performing them, with especial reference to Medico-Legal Practice. By Professor Rudolph Virchow, Berlin Charité Hospital. Translated by Dr. T. B. Smith. Second Edition, with 4 Plates. Feap. Svo. 3s. 6d.
- WILKS AND MOYON.—Lectures on Pathological Anatomy. By Samuel Wilks, M.D., F.R.S., Physician to, and Lecturer on Medicine at, Guy's Hospital; and Walter Moxon, M.D., F.R.C.P., Physician to, and Lecturer on Clinical Medicine at, Guy's Hospital. Second Edition. With 7 Steel Plates. Evo, 188.

PSYCHOLOGY.

BUCKNILL AND TUKE.—A Manual of Psycho-

logical Medicine: containing the Lunacy Laws, Nosology, Etiology, Statistics, Description, Diagnosis, Pathology, and Treatment of lusanity, with an Appendix of Cases. By John C. Bucknill, M.D., F.R.S., and D. HACK TUKE, M.D., F.R.C.P. Fourth Edition, with 12 Plates (30 Figures). Svo, 25s.

PHYSIOLOGY.

CARPENTER.-Principles of Human Physio-

logy. By William B. Carpenter, C.B., M.D., F.R.S. Ninth Edition. Edited by Henry Power, M.B., F.R.C.S. With 3 Steel Plates and 377 Wood Engravings. Svo, 31s. 6d.

DALTON.—A Treatise on Human Physiology:

designed for the use of Students and Practitioners of Medicine. By JOHN C. DALTON, M.D., Professor of Physiology and Hygiene in the College of Physicians and Surgeons, New York. Sixth Edition. With 316 Engravings. Royal 8vo, 20s.

FREY.—The Histology and Histo-Chemistry of

Man. A Treatise on the Elements of Composition and Structure of the Human Body. By Heinbien Frey, Professor of Medicine in Zurich. Translated by Arthur E. Barker, Assistant-Surgeon to the University College Hospital. With 608 Engavings. 8vo, 21s.

FULTON.—A Text-Book of Physiology, includ-

ing Histology. By J. Fulton, M.D., Professor of Physiology and Sanitary Science in Trinity Medical College, Toronto; Surgeon to the Toronto General Hospital. Secon Edition, with 151 Engravings. 8vo. 15s.

RUTHERFORD.—Outlines of Practical Histo-

logy. By WILLIAM RUTHERFORD, M.D., F.R.S., Professor of the Institutes of Medicine in the University of Edinburgh; Examiner in Physiology in the University of London. Third Edition. With Engravings. Crown 8vo (with additional leaves for Notes).

[In preparation.

SANDERSON.-Handbook for the Physiological

Laboratory: containing an Exposition of the fundamental facts of the Science, with explicit Directions for their demonstration. By J. Burdon Sanderson, M.D., F.R.S., Jodrell Professor of Physiology in University College; E. Klein, M.D., F.R.S., Assistant-Professor in the Brown Institution; Michael Foster, M.D., F.R.S., Prefector of Physiology at Trinity College, Cambridge; and T. Lauder Brunton, M.D., F.R.S., Lecturer on Materia Medica at St. Bartholomew's Hospital Medical College. 2 Vols., with 123 Plates. 8vo, 24s.

SURGERY.

- BRYANT. A Manual for the Practice of Surgery. By Thomas Bryant, F.R.C.S., Snrgeon to, and Lecturer on Surgery at, Guy's Hospital. Third Edition. With 672 Engravings (nearly all original, many being coloured). 2 vols. Crown Svo, 28s.
- BELLAMY.—The Student's Guide to Surgical Anatomy; a Description of the more important Surgical Regions of the Human Body, and an Introduction to Operative Surgery. By EDWARD BELLAMY, F.R.C.S., and Member of the Board of Examiners; Surgeon to, and Lecturer on Anatomy at, Charing Cross Hospital. Second Edition. With 76 Engravings. Fcap. Svo. 7s.
- CLARK AND WAGSTAFFE. Outlines of Surgery and Surgical Pathology. By F. Le Gros Clark, F.R.C.S., F.R.S., Consulting Surgeon to St. Thomas's Hospital. Second Edition. Revised and expanded by the Anthor, assisted by W. W. WAGSTAFFE, F.R.C.S., Assistant-Surgeon to St. Thomas's Hospital. Svo, 10s. 6d.
- DRUITT. The Surgeon's Vade-Mecum; a Manual of Modern Surgery. By ROBERT DRUITT, F.R.C.S. Eleventh Edition. With 369 Engravings. Fcap. 8vo, 14s.
- FERGUSSON.—A System of Practical Surgery.

 By Sir William Fergusson, Bart., F.R.C.S., F.R.S., late Surgeon and
 Professor of Clinical Surgery to King's College Hospital. With 463
 Eugravings. Fifth Edition. 8vo, 21s.
- HEATH.—A Manual of Minor Surgery and Bandaging, for the use of Honse-Surgeons, Dressers, and Junior Practitioners. By Christopher Heath, F.R.C.S., Holme Professor of Clinical Surgery in University College and Surgeon to the Hospital. Sixth Edition. With 115 Engravings, Fcap. Svo. 5s. 6d.

By the same Author.

A Course of Operative Surgery: with Twenty Plates drawn from Nature by M. Lévellé, and Coloured by hand under his direction. Large 8vo, 40s.

ALSO,

The Student's Guide to Surgical Diagnosis. Feap. 8vo, 6s. 6d.

SURGERY—continued.

- MAUNDER.—Operative Surgery. By Charles F. MAUNDER, F.R.C.S., late Surgeon to, and Lecturer on Surgery at, the London Hospital. Second Edition. With 164 Engravings. Post Svo, 6s.
- PIRRIE.—The Principles and Practice of Surgery. By WILLIAM PIRRIE, F.R.S.E., Professor of Surgery in the University of Aberdeen. Third Edition. With 490 Engravings. 8vo, 28s.

TERMINOLOGY.

- DUNGLISON.—Medical Lexicon: a Dictionary of Medical Science, containing a eoncise Explanation of its various Subjects and Terms, with Accentuation, Etymology, Synonymes, &c. By Robley Dunglison, M.D. New Edition, thoroughly revised by Richard J. Dunglison, M.D. Royal Svo, 28s.
- MAYNE.—A Medical Vocabulary: being an Explanation of all Terms and Phrases used in the various Departments of Medical Science and Practice, giving their Derivation, Meaning. Application, and Pronunciation. By ROBERT G. MAYNE, M.D., LL.D., and JOHN MAYNE, M.D., L.R.C.S.E. Fifth Edition. Feap. Svo, 10s. 6d.

WOMEN, DISEASES OF.

- BARNES.—A Clinical History of the Medical and Surgical Diseases of Women. By Robert Barnes, M.D., F.R.C.P., Obstetric Physician to, and Lecturer on Diseases of Women, &c., at, St. George's Hospital. Second Edition. With 181 Engravings. Svo, 28s.
- DUNCAN.—Clinical Lectures on the Diseases of Women. By J. MATTHEWS DUNCAN, M.D., Obstetric Physician to St. Bartholomew's Hospital. 8vo, 8s.
- EMMET. The Principles and Practice of Gynecology. By THOMAS ADDIS EMMET, M.D., Surgeon to the Woman's Hospital of the State of New York. With 130 Engravings. Royal Svo, 24s.

WOMEN, DISEASES OF-continued.

- CFALABIN.—The Student's Guide to the Disease of Women. By Alfred L. Galabin, M.D., F.R.C.P., Assistant Obstetric Physician and Joint Lecturer on Obstetric Medicine at Guy's Hospital. Second Edition. With 70 Engravings. Fcap. 8vo, 7s. 6d.
- REYNOLDS.—Notes on Diseases of Women.

 Specially designed for Students preparing for Examination. By J. J.

 REYNOLDS, M.R.C.S. Feap. 8vo, 2s. 6d.
- SMITH.—Practical Gynæcology: a Handbook of the Diseases of Women. By Herweod Smith, M.D., Physician to the Hospital for Women and to the British Lying-in Hospital. With Engravings. Crown 8vo, 5s. 6d.
- WEST AND DUNCAN.—Lectures on the Diseases of Women. By Charles West, M.D., F.R.C.P. Fourth Edition. Revised and in part re-written by the Author, with numerous additions, by J. Matthews Duncan, M.D., Obstetric Physician to St. Bartholomew's Hospital. Svo, 16s.

ZOOLOGY.

- BRADLEY.—Manual of Comparative Anatomy and Physiology. By S. Messenger Bradley, F.R.C.S., late Lecturer on Practical Surgery in Owen's College, Manchester. Third Edition. With 61 Engravings. Post Svo, 6s. 6d.
- CIIAUVEAU AND FLEMING.—The Comparative Anatomy of the Domesticated Animals. By A. Chauveau. Professor at the Lyons Veterinary School; and George Fleming. Veterinary Surgeon, Royal Engineers. With 450 Engravings. 8vo. 31s. 6d.
- HUXLEY.—Manual of the Anatomy of Invertebrated Animals. By Thomas H. Huxley, LL.D., F.R.S. With 156 Engravings. Fcap. 8vo, 16s.

By the same Author.

- Manual of the Anatomy of Vertebrated
 Auimals. With 110 Engravings, Post Svo, 12s.
- WILSON.—The Student's Guide to Zoology: a Manual of the Principles of Zoological Science. By Andrew Wilson, Lecturer on Natural History, Edinburgh. With Engravings. Feap. 8vo, 6s. 6d.
